$$\prod_{k=1,3,5,\dots}^{\infty} (1 + e^{-k\pi\sqrt{n}}) = 2^{1/4} e^{-\pi\sqrt{n}/24} G_n \quad (1)$$

$$\prod_{k=1,3,5,\dots}^{\infty} (1 - e^{-k\pi\sqrt{n}}) = 2^{1/4} e^{-\pi\sqrt{n}/24} g_n. \quad (2)$$

These satisfy the equalities

$$g_{4n} = 2^{1/4} g_n G_n \quad (3)$$

$$G_n = G_{1/n} \quad (4)$$

$$g_n^{-1} = g_{4/n} \quad (5)$$

$$\tfrac{1}{4} = (g_n G_n)^8 (G_n^8 - g_n^8). \quad (6)$$

$G_n$  and  $g_n$  can be derived using the theory of MODULAR FUNCTIONS and can always be expressed as roots of algebraic equations when  $n$  is RATIONAL. For simplicity, Ramanujan tabulated  $g_n$  for  $n$  EVEN and  $G_n$  for  $n$  ODD. However, (6) allows  $G_n$  and  $g_n$  to be solved for in terms of  $g_n$  and  $G_n$ , giving

$$g_n = \tfrac{1}{2} \left( G_n^8 + \sqrt{G_n^{16} - G_n^{-8}} \right)^{1/8} \quad (7)$$

$$G_n = \tfrac{1}{2} \left( g_n^8 + \sqrt{g_n^{16} + G_n^{-8}} \right)^{1/8}. \quad (8)$$

Using (3) and the above two equations allows  $g_{4n}$  to be computed in terms of  $g_n$  or  $G_n$

$$g_{4n} = \begin{cases} 2^{1/8} g_n \left( g_n^8 + \sqrt{g_n^{16} + g_n^{-8}} \right)^{1/8} & \text{for } n \text{ even} \\ 2^{1/8} G_n \left( G_n^8 + \sqrt{G_n^{16} - G_n^{-8}} \right)^{1/8} & \text{for } n \text{ odd.} \end{cases} \quad (9)$$

In terms of the PARAMETER  $k$  and complementary PARAMETER  $k'$ ,

$$G_n = (2knk')^{-1/12} \quad (10)$$

$$g_n = \left( \frac{k'^2}{2k} \right)^{1/12}. \quad (11)$$

Here,

$$k_n = \lambda^*(n) \quad (12)$$

is the ELLIPTIC LAMBDA FUNCTION, which gives the value of  $k$  for which

$$\frac{K'(k)}{K(k)} = \sqrt{n}. \quad (13)$$

Solving for  $\lambda^*(n)$  gives

$$\lambda^*(n) = \tfrac{1}{2} [\sqrt{1 + G_n^{-12}} - \sqrt{1 - G_n^{-12}}] \quad (14)$$

$$\lambda^*(n) = g_n^6 [\sqrt{g_n^{12} + g_n^{-12}} - g_n^6]. \quad (15)$$

Analytic values for small values of  $n$  can be found in Ramanujan (1913-1914) and Borwein and Borwein (1987), and have been compiled in Weisstein (1996). Ramanujan (1913-1914) contains a typographical error labeling  $G_{465}$  as  $G_{265}$ .

## Ramanujan's Interpolation Formula

$$\int_0^{\infty} x^{s-1} \sum_{k=0}^{\infty} (-1)^k x^k \phi(k) dx = \frac{\pi \phi(-s)}{\sin(s\pi)} \quad (1)$$

$$\int_0^{\infty} x^{s-1} \sum_{k=0}^{\infty} (-1)^k \frac{x^k}{k!} \lambda(k) dx = \Gamma(s) \lambda(-s), \quad (2)$$

where  $\lambda(z)$  is the DIRICHLET LAMBDA FUNCTION and  $\Gamma(z)$  is the GAMMA FUNCTION. Equation (2) is obtained from (1) by defining

$$\phi(u) = \frac{\lambda(u)}{\Gamma(1+u)}. \quad (3)$$

These formulas give valid results only for certain classes of functions.

## Ramanujan-Petersson Conjecture

A CONJECTURE for the EIGENVALUES of modular forms under HECKE OPERATORS.

## Ramanujan Psi Sum

A sum which includes both the JACOBI TRIPLE PRODUCT and the  $q$ -BINOMIAL THEOREM as special cases. Ramanujan's sum is

$$\sum_{n=-\infty}^{\infty} \frac{(a)_n}{(b)_n} x^n = \frac{(ax)_{\infty} (q/ax)_{\infty} (q)_{\infty} (b/a)_{\infty}}{(x)_{\infty} (b/ax)_{\infty} (b)_{\infty} (q/a)_{\infty}},$$

where the NOTATION  $(q)_k$  denotes  $q$ -SERIES. For  $b = q$ , this becomes the  $q$ -BINOMIAL THEOREM.

see also JACOBI TRIPLE PRODUCT,  $q$ -BINOMIAL THEOREM,  $q$ -SERIES

**Ramanujan's Square Equation**

It has been proved that the only solutions to the DIO-PHANTINE EQUATION

$$2^n - 7 = x^2$$

are  $n = 3, 4, 5, 7$ , and  $15$  (Beeler *et al.* 1972, Item 31).

**References**

Beeler, M.; Gosper, R. W.; and Schroepel, R. *HAKMEM*. Cambridge, MA: MIT Artificial Intelligence Laboratory, Memo AIM-239, Feb. 1972.

**Ramanujan's Sum**

The sum

$$c_q(m) = \sum_{h^*(q)} e^{2\pi i h m / q}, \quad (1)$$

where  $h$  runs through the residues RELATIVELY PRIME to  $q$ , which is important in the representation of numbers by the sums of squares. If  $(q, q') = 1$  (i.e.,  $q$  and  $q'$  are RELATIVELY PRIME), then

$$c_{qq'}(m) = c_q(m)c_{q'}(m). \quad (2)$$

For argument 1,

$$c_b(1) = \mu(b), \quad (3)$$

where  $\mu$  is the MÖBIUS FUNCTION, and for general  $m$ ,

$$c_b(m) = \mu\left(\frac{b}{(b, m)}\right) \frac{\phi(b)}{\phi\left(\frac{b}{(b, m)}\right)}. \quad (4)$$

see also MÖBIUS FUNCTION, WEYL'S CRITERION

**References**

Vardi, I. *Computational Recreations in Mathematica*. Redwood City, CA: Addison-Wesley, p. 254, 1991.

**Ramanujan's Sum Identity**

If

$$\frac{1 + 53x + 9x^2}{1 - 82x - 82x^2 + x^3} = \sum_{n=1}^{\infty} a_n x^n \quad (1)$$

$$\frac{2 - 26x - 12x^2}{1 - 82x - 82x^2 + x^3} = \sum_{n=0}^{\infty} b_n x^n \quad (2)$$

$$\frac{2 + 8x - 10x^2}{1 - 82x - 82x^2 + x^3} = \sum_{n=0}^{\infty} c_n x^n, \quad (3)$$

then

$$a_n^3 + b_n^3 = c_n^3 + (-1)^n. \quad (4)$$

Hirschhorn (1995) showed that

$$a_n = \frac{1}{85}[(64 + 8\sqrt{85})\alpha^n + (64 - 8\sqrt{85})\beta^n - 43(-1)^n] \quad (5)$$

$$b_n = \frac{1}{85}[(77 + 7\sqrt{85})\alpha^n + (77 - 7\sqrt{85})\beta^n + 16(-1)^n] \quad (6)$$

$$c_n = \frac{1}{85}[(93 + 9\sqrt{85})\alpha^n + (93 - 9\sqrt{85})\beta^n - 16(-1)^n], \quad (7)$$

where

$$\alpha = \frac{1}{2}(83 + 9\sqrt{85}) \quad (8)$$

$$\beta = \frac{1}{2}(83 - 9\sqrt{85}). \quad (9)$$

Hirschhorn (1996) showed that checking the first seven cases  $n = 0$  to  $6$  is sufficient to prove the result.

**Ramanujan Theta Functions**

Ramanujan's one-variable theta function is defined by

$$\varphi(x) \equiv \sum_{m=-\infty}^{\infty} x^{m^2}. \quad (1)$$

It is equal to the function in the JACOBI TRIPLE PRODUCT with  $z = 1$ ,

$$\begin{aligned} \varphi(x) &= G(1) = \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 (1 - x^{2n}) \\ &= \sum_{m=-\infty}^{\infty} x^{m^2} = 1 + 2 \sum_{m=0}^{\infty} x^{m^2}. \end{aligned} \quad (2)$$

Special values include

$$\varphi(e^{-\pi\sqrt{2}}) = \frac{\Gamma(\frac{9}{8})}{\Gamma(\frac{5}{4})} \sqrt{\frac{\Gamma(\frac{1}{4})}{2^{1/4}\pi}} \quad (3)$$

$$\varphi(e^{-\pi}) = \frac{\pi^{1/4}}{\Gamma(\frac{3}{4})} \quad (4)$$

$$\varphi(e^{-2\pi}) = \frac{\sqrt{2 + \sqrt{2}}}{2} \frac{\pi}{\Gamma(\frac{3}{4})}. \quad (5)$$

Ramanujan's two-variable theta function is defined by

$$f(a, b) \equiv \sum_{n=-\infty}^{\infty} a^{n(n+1)/2} b^{n(n-1)/2} \quad (6)$$

for  $|ab| < 1$ . It satisfies

$$f(-1, a) = 0 \quad (7)$$

$$f(a, b) = f(b, a) = (-a; ab)_{\infty} (-b; ab)_{\infty} (ab; ab)_{\infty} \quad (8)$$

$$f(-q) \equiv f(-q, -q^2) \\ = \sum_{k=0}^{\infty} (-1)^k q^{k(2k-1)/2} + \sum_{k=1}^{\infty} (-1)^k q^{k(2k+1)/2} \\ = (q; q)_{\infty}, \quad (9)$$

where  $(q)_{\infty}$  are  $q$ -SERIES.

see also JACOBI TRIPLE PRODUCT, SCHRÖTER'S FORMULA,  $q$ -SERIES

## Ramp Function

$$R(x) \equiv xH(x) \quad (1)$$

$$= \int_{-\infty}^x H(x') dx' \quad (2)$$

$$= \int_{-\infty}^{\infty} H(x') H(x - x') dx' \quad (3)$$

$$= H(x) * H(x), \quad (4)$$

where  $H(x)$  is the HEAVISIDE STEP FUNCTION and  $*$  is the CONVOLUTION. The DERIVATIVE is

$$R'(x) = -H(x). \quad (5)$$

The FOURIER TRANSFORM of the ramp function is given by

$$\mathcal{F}[R(x)] = \int_{-\infty}^{\infty} e^{-2\pi i k x} R(x) dx = \pi i \delta'(2\pi k) - \frac{1}{4\pi^2 k^2}, \quad (6)$$

where  $\delta(x)$  is the DELTA FUNCTION and  $\delta'(x)$  its DERIVATIVE.

see also FOURIER TRANSFORM—RAMP FUNCTION, HEAVISIDE STEP FUNCTION, RECTANGLE FUNCTION, SGN, SQUARE WAVE

## Ramphoid Cusp

A type of CUSP as illustrated above for the curve  $x^4 + x^2 y^2 - 2x^2 y - xy^2 + y^2 = 0$ .

see also CUSP

## Ramsey Number

The Ramsey number  $R(m, n)$  gives the solution to the PARTY PROBLEM, which asks the minimum number of guests  $R(m, n)$  that must be invited so that at least  $m$  will know each other (i.e., there exists a CLIQUE of order  $m$ ) or at least  $n$  will not know each other (i.e., there exists an independent set of order  $n$ ). By symmetry, it is true that

$$R(m, n) = R(n, m). \quad (1)$$

It also must be true that

$$R(2, m) = m. \quad (2)$$

A generalized Ramsey number is written

$$R(m_1, \dots, m_k; n) \quad (3)$$

and is the smallest INTEGER  $R$  such that, no matter how each  $n$ -element SUBSET of an  $r$ -element SET are colored with  $k$  colors, there exists an  $i$  such that there is a SUBSET of size  $m_i$ , all of whose  $n$ -element SUBSETS are color  $i$ . The usual Ramsey numbers are then equivalent to  $R(m, n) = R(m, n; 2)$ .

Bounds are given by

$$R(k, l) \leq \begin{cases} R(k-1, l) + R(k, l-1) - 1 & \text{for } R(k-1, l) \text{ and} \\ & R(k, l-1) \text{ even} \\ R(k-1, l) + R(k, l-1) & \text{otherwise} \end{cases} \quad (4)$$

and

$$R(k, k) \leq 4R(k-2, k) + 2 \quad (5)$$

(Chung and Grinstead 1983). Erdős proved that for diagonal Ramsey numbers  $R(k, k)$ ,

$$\frac{k2^{k/2}}{e\sqrt{2}} < R(k, k). \quad (6)$$

This result was subsequently improved by a factor of 2 by Spencer (1975).  $R(3, k)$  was known since 1980 to be bounded from above by  $c_2 k^2 / \ln k$ , and Griggs (1983) showed that  $c_2 = 5/12$  was an acceptable limit. J.-H. Kim (Cipra 1995) subsequently bounded  $R(3, k)$  by a similar expression from below, so

$$c_1 \frac{k^2}{\ln k} \leq R(3, k) \leq c_2 \frac{k^2}{\ln k}. \quad (7)$$

Burr (1983) gives Ramsey numbers for all 113 graphs with no more than 6 EDGES and no isolated points.

A summary of known results up to 1983 for  $R(m, n)$  is given in Chung and Grinstead (1983). Radziszowski maintains an up-to-date list of the best current bounds, reproduced in part in the following table for  $R(m, n; 2)$ .

$m$	$n$	$R(m, n)$
3	3	6
3	4	9
3	5	14
3	6	18

## Ramsey's Theorem

A generalization of DILWORTH'S LEMMA. For each  $m, n \in \mathbb{N}$  with  $m, n \geq 2$ , there exists a least INTEGER  $R(m, n)$  (the RAMSEY NUMBER) such that no matter how the COMPLETE GRAPH  $K_{R(m, n)}$  is two-colored, it

will contain a green SUBGRAPH  $K_m$  or a red subgroup  $K_n$ . Furthermore,

$$R(m, n) \leq R(m - 1, n) + R(m, n - 1)$$

if  $m, n \geq 3$ . The theorem can be equivalently stated that, for all  $n \in \mathbb{N}$ , there exists an  $n \in \mathbb{N}$  such that any complete DIGRAPH on  $n$  VERTICES contains a complete transitive SUBGRAPH of  $m$  VERTICES. Ramsey's theorem is a generalization of the PIGEONHOLE PRINCIPLE since

$$R(\underbrace{2, 2, \dots, 2}_t) = t + 1.$$

## Randelbrot Set

The FRACTAL-like figure obtained by performing the same iteration as for the MANDELBROT SET, but adding a random component  $R$ ,

$$z_{n+1} = z_n^2 + c + R.$$

In the above plot,  $R \equiv R_x + iR_y$ , where  $R_x, R_y \in [-0.05, 0.05]$ .

## Random Distribution

A DISTRIBUTION in which the variates occur with PROBABILITIES asymptotically matching their "true" underlying DISTRIBUTION is said to be random.

see also DISTRIBUTION, RANDOM NUMBER

**Random Dot Stereogram**

see STEREOGRAM

**Random Graph**

A random graph is a GRAPH in which properties such as the number of NODES, EDGES, and connections between them are determined in some random way. Erdős and Rényi showed that for many monotone-increasing properties of random graphs, graphs of a size slightly less than a certain threshold are very unlikely to have the property, whereas graphs with a few more EDGES are almost certain to have it. This is known as a PHASE TRANSITION.

**Random Matrix**

A random matrix is a MATRIX of given type and size whose entries consist of random numbers from some specified distribution.

see also MATRIX

**Random Number**

Computer-generated random numbers are sometimes called PSEUDORANDOM NUMBERS, while the term "random" is reserved for the output of unpredictable physical processes. It is impossible to produce an arbitrarily long string of random digits and prove it is random. Strangely, it is very difficult for humans to produce a string of random digits, and computer programs can be written which, on average, actually predict some of the digits humans will write down based on previous ones.

The LINEAR CONGRUENCE METHOD is one algorithm for generating PSEUDORANDOM NUMBERS. The initial number used as the starting point in a random number generating algorithm is known as the SEED. The goodness of random numbers generated by a given ALGORITHM can be analyzed by examining its NOISE SPHERE.

**Random Walk**

A random process consisting of a sequence of discrete steps of fixed length. The random thermal perturbations in a liquid are responsible for a random walk phenomenon known as Brownian motion, and the collisions of molecules in a gas are a random walk responsible for diffusion. Random walks have interesting mathematical

properties that vary greatly depending on the dimension in which the walk occurs and whether it is confined to a lattice.

### Random Walk—1-D

Let  $N$  steps of equal length be taken along a LINE. Let  $p$  be the probability of taking a step to the right,  $q$  the probability of taking a step to the left,  $n_1$  the number of steps taken to the right, and  $n_2$  the number of steps taken to the left. The quantities  $p$ ,  $q$ ,  $n_1$ ,  $n_2$ , and  $N$  are related by

$$p + q = 1 \quad (1)$$

and

$$n_1 + n_2 = N. \quad (2)$$

Now examine the probability of taking exactly  $n_1$  steps out of  $N$  to the right. There are  $\binom{N}{n_1} = \binom{n_1+n_2}{n_1}$  ways of taking  $n_1$  steps to the right and  $n_2$  to the left, where  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT. The probability of taking a particular ordered sequence of  $n_1$  and  $n_2$  steps is  $p^{n_1}q^{n_2}$ . Therefore,

$$P(n_1) = \frac{(n_1 + n_2)!}{n_1!n_2!} p^{n_1} q^{n_2} = \frac{N!}{n_1!(N - n_1)!} p^{n_1} q^{N - n_1}, \quad (3)$$

where  $n!$  is a FACTORIAL. This is a BINOMIAL DISTRIBUTION and satisfies

$$\sum_{n_1=0}^N P(n_1) = (p + q)^N = 1^N = 1. \quad (4)$$

The MEAN number of steps  $n_1$  to the right is then

$$\langle n_1 \rangle \equiv \sum_{n_1=0}^N n_1 P(n_1) = \sum_{n_1=0}^N \frac{N!}{n_1!(N - n_1)!} p^{n_1} q^{N - n_1} n_1, \quad (5)$$

but

$$n_1 p^{n_1} = p \frac{\partial}{\partial p} p^{n_1}, \quad (6)$$

so

$$\begin{aligned} \langle n_1 \rangle &= \sum_{n_1=0}^N \frac{N!}{n_1!(N - n_1)!} \left( p \frac{\partial}{\partial p} p^{n_1} \right) q^{N - n_1} \\ &= p \frac{\partial}{\partial p} \sum_{n_1=0}^N \frac{N!}{n_1!(N - n_1)!} p^{n_1} q^{N - n_1} \\ &= p \frac{\partial}{\partial p} (p + q)^N = p N (p + q)^{N-1} = p N. \end{aligned} \quad (7)$$

From the BINOMIAL THEOREM,

$$\langle n_2 \rangle = N - \langle n_1 \rangle = N(1 - p) = qN. \quad (8)$$

The VARIANCE is given by

$$\sigma_{n_1}^2 = \langle n_1^2 \rangle - \langle n_1 \rangle^2. \quad (9)$$

But

$$\langle n_1^2 \rangle = \sum_{n_1=0}^N \frac{N!}{n_1!(N - n_1)!} p^{n_1} q^{N - n_1} n_1^2, \quad (10)$$

so

$$\begin{aligned} n_1^2 p^{n_1} &= n_1 \left( p \frac{\partial}{\partial p} \right) p^{n_1} = \left( p \frac{\partial}{\partial p} \right)^2 p^{n_1} \\ &= \sum_{n_1=0}^N \frac{N!}{n_1!(N - n_1)!} \left( p \frac{\partial}{\partial p} \right)^2 p^{n_1} q^{N - n_1} \\ &= \left( p \frac{\partial}{\partial p} \right)^2 \sum_{n_1=0}^N \frac{N!}{n_1!(N - n_1)!} p^{n_1} q^{N - n_1} \\ &= \left( p \frac{\partial}{\partial p} \right)^2 (p + q)^N = \frac{\partial}{\partial p} [pN(p + q)N - 1] \\ &= p[N(p + q)^{N-1} + pN(N - 1)(p + q)^{N-2}] \\ &= p[N + pN(N - 1)] \\ &= pN[1 + pN - p] = (Np)^2 + Npq \\ &= \langle n_1 \rangle^2 + Npq. \end{aligned} \quad (11)$$

Therefore,

$$\sigma_{n_1}^2 = \langle n_1^2 \rangle - \langle n_1 \rangle^2 = Npq, \quad (12)$$

and the ROOT-MEAN-SQUARE deviation is

$$\sigma_{n_1} = \sqrt{Npq}. \quad (13)$$

For a large number of total steps  $N$ , the BINOMIAL DISTRIBUTION characterizing the distribution approaches a GAUSSIAN DISTRIBUTION.

Consider now the distribution of the distances  $d_N$  traveled after a given number of steps,

$$d_N \equiv n_1 - n_2 = 2n_1 - N, \quad (14)$$

as opposed to the *number* of steps in a given direction. The above plots show  $d_N(p)$  for  $N = 200$  and three values  $p = 0.1$ ,  $p = 0.5$ , and  $p = 0.9$ , respectively. Clearly, weighting the steps toward one direction or the other influences the overall trend, but there is still a great deal of random scatter, as emphasized by the plot below, which shows three random walks all with  $p = 0.5$ .

Surprisingly, the most probable number of sign changes in a walk is 0, followed by 1, then 2, etc.

For a random walk with  $p = 1/2$ , the probability  $P_N(d)$  of traveling a given distance  $d$  after  $N$  steps is given in the following table.

steps	-5	-4	-3	-2	-1	0	1	2	3	4	5
0						1					
1					$\frac{1}{2}$	0	$\frac{1}{2}$				
2				$\frac{1}{4}$	0	$\frac{2}{4}$	0	$\frac{1}{4}$			
3			$\frac{1}{8}$	0	$\frac{3}{8}$	0	$\frac{3}{8}$	0	$\frac{1}{8}$		
4		$\frac{1}{16}$	0	$\frac{4}{16}$	0	$\frac{6}{16}$	0	$\frac{4}{16}$	0	$\frac{1}{16}$	
5	$\frac{1}{32}$	0	$\frac{5}{32}$	0	$\frac{10}{32}$	0	$\frac{10}{32}$	0	$\frac{5}{32}$	0	$\frac{1}{32}$

In this table, subsequent rows are found by adding HALF of each cell in a given row to each of the two cells diagonally below it. In fact, it is simply PASCAL'S TRIANGLE padded with intervening zeros and with each row multiplied by an additional factor of  $1/2$ . The COEFFICIENTS in this triangle are given by

$$P_N(d) = \frac{1}{2^N} \binom{N}{\frac{d+N}{2}}. \quad (15)$$

The expectation value of the distance after  $N$  steps is therefore

$$\begin{aligned} \langle d_N \rangle &= \sum_{d=-N, -(N-2), \dots}^N |d| P_N(d) \\ &= \frac{1}{2^N} \sum_{d=-N, -(N-2), \dots}^N \frac{|d| N!}{\left(\frac{N+d}{2}\right)! \left(\frac{N-d}{2}\right)!}. \end{aligned} \quad (16)$$

This sum can be done symbolically by separately considering the cases  $N$  EVEN and  $N$  ODD. First, consider EVEN  $N$  so that  $N \equiv 2J$ . Then

$$\begin{aligned} \langle d_{2J} \rangle &= \frac{N!}{2^N} \left[ \sum_{d=-2J, -2(J-1), \dots}^{-2} \frac{|d|}{\left(\frac{2J+d}{2}\right)! \left(\frac{2J-d}{2}\right)!} \right. \\ &\quad \left. + \sum_{d=0} \frac{|d|}{\left(\frac{2J+d}{2}\right)! \left(\frac{2J-d}{2}\right)!} + \sum_{d=2, 4, \dots}^{2J} \frac{|d|}{\left(\frac{2J+d}{2}\right)! \left(\frac{2J-d}{2}\right)!} \right] \\ &= \frac{N!}{2^N} \left[ \sum_{d=-J, -(J-1), \dots}^{-1} \frac{|2d|}{\left(\frac{2J+2d}{2}\right)! \left(\frac{2J-2d}{2}\right)!} \right. \\ &\quad \left. + \sum_{d=1, 2, \dots}^J \frac{|2d|}{\left(\frac{2J+2d}{2}\right)! \left(\frac{2J-2d}{2}\right)!} \right] \\ &= \frac{N!}{2^N} \left[ 2 \sum_{d=1}^J \frac{2d}{(J+d)!(J-d)!} \right] \\ &= \frac{N!}{2^{N-2}} \sum_{d=1}^J \frac{d}{(J+d)!(J-d)!}. \end{aligned} \quad (17)$$

But this sum can be evaluated analytically as

$$\sum_{d=1}^J \frac{d}{(J+d)!(J-d)!} = \frac{J}{2\Gamma^2(1+J)}, \quad (18)$$

which, when combined with  $N = 2J$  and plugged back in, gives

$$\langle d_{2J} \rangle = \frac{\Gamma(2J+1)J}{2^{2J-1}\Gamma^2(1+J)} = \frac{\Gamma(2J)}{2^{2J-2}\Gamma^2(J)}. \quad (19)$$

But the LEGENDRE DUPLICATION FORMULA gives

$$\Gamma(2J) = \frac{2^{2J-1/2}\Gamma(J)\Gamma(J+\frac{1}{2})}{\sqrt{2\pi}}, \quad (20)$$

so

$$\langle d_{2J} \rangle = \frac{\frac{1}{\sqrt{2\pi}} 2^{2J-1/2} \Gamma(J)\Gamma(J+\frac{1}{2})}{2^{2J-2}\Gamma^2(J)} = \frac{2}{\sqrt{\pi}} \frac{\Gamma(J+\frac{1}{2})}{\Gamma(J)}. \quad (21)$$

Now consider  $N$  ODD, so  $N \equiv 2J - 1$ . Then

$$\begin{aligned}
 \langle d_{2J-1} \rangle &= \frac{N!}{2^N} \left[ \sum_{d=-(2J-1), \dots, -(2J+1), \dots}^{-1} \frac{|d|}{\left(\frac{2J-1+d}{2}\right)! \left(\frac{2J-1-d}{2}\right)!} \right. \\
 &\quad \left. + \sum_{d=1,3,\dots}^{2J-1} \frac{|d|}{\left(\frac{2J-1+d}{2}\right)! \left(\frac{2J-1-d}{2}\right)!} \right] \\
 &= \frac{N!}{2^{N-1}} \left[ \sum_{d=1,3,\dots}^{2J-1} \frac{d}{\left(\frac{2J-1+d}{2}\right)! \left(\frac{2J-1-d}{2}\right)!} \right] \\
 &= \frac{N!}{2^{N-1}} \left[ \sum_{d=2,4,\dots}^{2J} \frac{d-1}{\left(\frac{2J-2+d}{2}\right)! \left(\frac{2J-d}{2}\right)!} \right] \\
 &= \frac{\Gamma(2J)}{2^{2J-2}} \left[ \sum_{d=1}^J \frac{2d-1}{(J+d-1)!(J-d)!} \right] \\
 &= \Gamma(2J) \left[ \frac{1+J-{}_2F_1(1, -J; J; 1)}{2^{2J-2}\Gamma(J)\Gamma(1+J)} + \frac{1}{\Gamma(2J)} \right] \\
 &= \frac{2^{2J-1/2}}{\sqrt{2\pi}} \frac{\Gamma(J)\Gamma(J+1/2)}{2^{2J-2}\Gamma^2(J)} [1+J-{}_2F_1(1, -J; J; -1)] + 1 \\
 &= \frac{2}{\sqrt{\pi}} \frac{\Gamma(J+\frac{1}{2})}{J\Gamma(J)} [1+J-{}_2F_1(1, -J; J; -1)] + 1. \quad (22)
 \end{aligned}$$

But the HYPERGEOMETRIC FUNCTION  ${}_2F_1$  has the special value

$${}_2F_1(1, -J; J; -1) = \frac{\sqrt{\pi}}{2} \frac{J\Gamma(J)}{\Gamma(J+\frac{1}{2})} + 1, \quad (23)$$

so

$$\langle d_{2J-1} \rangle = \frac{2}{\sqrt{\pi}} \frac{\Gamma(J+\frac{1}{2})}{\Gamma(J)}. \quad (24)$$

Summarizing the EVEN and ODD solutions,

$$\langle d_N \rangle = \frac{2}{\sqrt{\pi}} \frac{\Gamma(J+\frac{1}{2})}{\Gamma(J)}, \quad (25)$$

where

$$\begin{cases} J = \frac{1}{2}N & \text{for } N \text{ even} \\ J = \frac{1}{2}(N+1) & \text{for } N \text{ odd.} \end{cases} \quad (26)$$

Written explicitly in terms of  $N$ ,

$$\langle d_N \rangle = \begin{cases} \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{1}{2}N+\frac{1}{2})}{\Gamma(\frac{1}{2}N)} & \text{for } N \text{ even} \\ \frac{2}{\sqrt{\pi}} \frac{\Gamma(\frac{1}{2}N+1)}{\Gamma(\frac{1}{2}N+\frac{1}{2})} & \text{for } N \text{ odd.} \end{cases} \quad (27)$$

The first few values of  $\langle d_N \rangle$  are then

$$\begin{aligned}
 \langle d_0 \rangle &= 0 \\
 \langle d_1 \rangle &= \langle d_2 \rangle = 1 \\
 \langle d_3 \rangle &= \langle d_4 \rangle = \frac{3}{2} \\
 \langle d_5 \rangle &= \langle d_6 \rangle = \frac{15}{8} \\
 \langle d_7 \rangle &= \langle d_8 \rangle = \frac{35}{16} \\
 \langle d_9 \rangle &= \langle d_{10} \rangle = \frac{315}{128} \\
 \langle d_{11} \rangle &= \langle d_{12} \rangle = \frac{693}{256} \\
 \langle d_{13} \rangle &= \langle d_{14} \rangle = \frac{3003}{1024}.
 \end{aligned}$$

Now, examine the asymptotic behavior of  $\langle d_N \rangle$ . The asymptotic expansion of the GAMMA FUNCTION ratio is

$$\frac{\Gamma(J+\frac{1}{2})}{\Gamma(J)} = \sqrt{J} \left( 1 - \frac{1}{8J} + \frac{1}{128J^2} + \dots \right) \quad (28)$$

(Graham *et al.* 1994), so plugging in the expression for  $\langle d_N \rangle$  gives the asymptotic series

$$\begin{aligned}
 \langle d_N \rangle &= \sqrt{\frac{2N}{\pi}} \left( 1 \mp \frac{1}{4N} + \frac{1}{32N^2} \pm \frac{5}{128N^3} \right. \\
 &\quad \left. - \frac{21}{2048N^4} \mp \dots \right), \quad (29)
 \end{aligned}$$

where the top signs are taken for  $N$  EVEN and the bottom signs for  $N$  ODD. Therefore, for large  $N$ ,

$$\langle d_N \rangle \sim \sqrt{\frac{2N}{\pi}}, \quad (30)$$

which is also shown in Mosteller *et al.* (1961, p. 14).

## Random Walk—2-D

In a PLANE, consider a sum of  $N$  2-D VECTORS with random orientations. Use PHASOR notation, and let the phase of each VECTOR be RANDOM. Assume  $N$  unit steps are taken in an arbitrary direction (i.e., with the angle  $\theta$  uniformly distributed in  $[0, 2\pi)$  and *not* on a LATTICE), as illustrated above. The position  $z$  in the COMPLEX PLANE after  $N$  steps is then given by

$$z = \sum_{j=1}^N e^{i\theta_j}, \quad (1)$$

which has ABSOLUTE SQUARE

$$\begin{aligned} |z|^2 &= \sum_{j=1}^N e^{i\theta_j} \sum_{k=1}^N e^{-i\theta_k} = \sum_{j=1}^N \sum_{k=1}^N e^{i(\theta_j - \theta_k)} \\ &= N + \sum_{\substack{j,k=1 \\ k \neq j}}^N e^{i(\theta_j - \theta_k)}. \end{aligned} \quad (2)$$

Therefore,

$$\langle |z|^2 \rangle = N + \left\langle \sum_{\substack{j,k=1 \\ k \neq j}}^N e^{i(\theta_j - \theta_k)} \right\rangle. \quad (3)$$

Each step is likely to be in any direction, so both  $\theta_j$  and  $\theta_k$  are RANDOM VARIABLES with identical MEANS of zero, and their difference is also a random variable. Averaging over this distribution, which has equally likely POSITIVE and NEGATIVE values yields an expectation value of 0, so

$$\langle |z|^2 \rangle = N. \quad (4)$$

The root-mean-square distance after  $N$  unit steps is therefore

$$|z|_{\text{rms}} = \sqrt{N}, \quad (5)$$

so with a step size of  $l$ , this becomes

$$d_{\text{rms}} = l\sqrt{N}. \quad (6)$$

In order to travel a distance  $d$

$$N \approx \left( \frac{d}{l} \right)^2 \quad (7)$$

steps are therefore required.

Amazingly, it has been proven that on a 2-D LATTICE, a random walk has unity probability of reaching any point (including the starting point) as the number of steps approaches INFINITY.

see also PÓLYA'S RANDOM WALK CONSTANTS, RANDOM WALK—1-D, RANDOM WALK—3-D

## Random Walk—3-D

On a 3-D LATTICE, a random walk has *less than* unity probability of reaching any point (including the starting point) as the number of steps approaches infinity. The probability of reaching the starting point again is 0.3405373296.... This is one of PÓLYA'S RANDOM WALK CONSTANTS.

see also PÓLYA'S RANDOM WALK CONSTANTS, RANDOM WALK—1-D, RANDOM WALK—2-D

## Range (Image)

If  $T$  is MAP over a DOMAIN  $D$ , then the range of  $T$  is defined as

$$\text{Range}(T) = T(D) = \{T(\mathbf{X}) : \mathbf{X} \in D\}.$$

The range  $T(D)$  is also called the IMAGE of  $D$  under  $T$ .

see also DOMAIN, MAP

**Range (Line Segment)**

The set of all points on a LINE SEGMENT, also called a PENCIL.

see also PERSPECTIVITY, SECTION (PENCIL)

**References**

Woods, F. S. *Higher Geometry: An Introduction to Advanced Methods in Analytic Geometry*. New York: Dover, p. 8, 1961.

**Range (Statistics)**

$$R \equiv \max(x_i) - \min(x_i). \quad (1)$$

For small samples, the range is a good estimator of the population STANDARD DEVIATION (Kenney and Keeping 1962, pp. 213–214). For a continuous UNIFORM DISTRIBUTION

$$P(x) = \begin{cases} \frac{1}{C} & \text{for } 0 < x < C \\ 0 & \text{for } |x| < C, \end{cases} \quad (2)$$

the distribution of the range is given by

$$D(R) = N \left( \frac{R}{C} \right)^{N-1} - (N-1) \left( \frac{R}{C} \right)^N. \quad (3)$$

Given two samples with sizes  $m$  and  $n$  and ranges  $R_1$  and  $R_2$ , let  $u \equiv R_1/R_2$ . Then

$$D(u) = \begin{cases} \frac{m(m-1)n(n-1)}{(m+n)(m+n-1)(m+n-2)} \\ \times [(m+n)u^{m-2} - (m+n-2)u^{m-1}] & \text{for } 0 \leq u \leq 1 \\ \frac{m(m-1)n(n-1)}{(m+n)(m+n-1)(m+n-2)} \\ \times [(m+n)u^{-n} - (m+n-2)u^{-n-1}] & \text{for } 1 \leq u < \infty. \end{cases} \quad (4)$$

The MEAN is

$$\mu_u = \frac{(m-1)n}{(m+1)(n-2)}, \quad (5)$$

and the MODE is

$$\hat{u} = \begin{cases} \frac{(m-2)(m+n)}{(m-1)(m+n-2)} & \text{for } m-n \leq 2 \\ \frac{(n+1)(m+n-2)}{n(m+n)} & \text{for } m-n \geq 2. \end{cases} \quad (6)$$

**Rank**

In a total generality, the “rank” of a mathematical object is defined whenever that object is FREE. In general, the rank of a FREE object is the CARDINALITY of the FREE generating SUBSET  $G$ . The word “rank” also refers to several unrelated concepts in mathematics involving groups, quadratic forms, sequences, statistics, and tensors.

see also RANK (GROUP), RANK (QUADRATIC FORM), RANK (SEQUENCE), RANK (STATISTICS), RANK (TENSOR)

**Rank (Group)**

For an arbitrary finitely generated ABELIAN GROUP  $G$ , the rank of  $G$  is defined to be the rank of the FREE generating SUBSET  $G$  modulo its TORSION SUBGROUP. For a finitely generated GROUP, the rank is defined to be the rank of its “Abelianization.”

see also ABELIAN GROUP, BETTI NUMBER, BURNSIDE PROBLEM, QUASITHIN THEOREM, QUASI-UNIPOTENT GROUP, TORSION (GROUP THEORY)

**Rank (Quadratic Form)**

For a QUADRATIC FORM  $Q$  in the canonical form

$$Q = y_1^2 + y_2^2 + \dots + y_p^2 - y_{p+1}^2 - y_{p+2}^2 - \dots - y_r^2,$$

the rank is the total number  $r$  of square terms (both POSITIVE and NEGATIVE).

see also SIGNATURE (QUADRATIC FORM)

**References**

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products, 5th ed.* San Diego, CA: Academic Press, p. 1105, 1979.

**Rank (Sequence)**

The position of a RATIONAL NUMBER in the SEQUENCE  $1, \frac{1}{2}, 2, \frac{1}{3}, 3, \frac{1}{4}, \frac{2}{3}, \frac{3}{2}, 4, \frac{1}{5}, \dots$ , ordered in terms of increasing NUMERATOR+DENOMINATOR.

see also ENCODING, FAREY SERIES

**Rank (Statistics)**

The ORDINAL NUMBER of a value in a list arranged in a specified order (usually decreasing).

see also SPEARMAN RANK CORRELATION, WILCOXON RANK SUM TEST, WILCOXON SIGNED RANK TEST, ZIPF'S LAW

**Rank (Tensor)**

The total number of CONTRAVARIANT and COVARIANT indices of a TENSOR. The rank of a TENSOR is independent of the number of DIMENSIONS of the SPACE.

Rank	Object
0	scalar
1	vector
$\geq 2$	tensor

see also CONTRAVARIANT TENSOR, COVARIANT TENSOR, SCALAR, TENSOR, VECTOR

**Ranunculoid**

An EPICYCLOID with  $n = 5$  cusps, named after the buttercup genus *Ranunculus* (Madachy 1979).

see also EPICYCLOID.

### RAT-Free Set

A RAT-free set is a set of points, no three of which determine a RIGHT TRIANGLE. Let  $f(n)$  be the smallest RAT-free subset guaranteed to be contained in a planar set of  $n$  points, then the function  $f(n)$  is bounded by

$$\sqrt{n} \leq f(n) \leq 2\sqrt{n}.$$

### Ratio

The ratio of two numbers  $r$  and  $s$  is written  $r/s$ , where  $r$  is the NUMERATOR and  $s$  is the DENOMINATOR. The ratio of  $r$  to  $s$  is equivalent to the QUOTIENT  $r/s$ . Betting ODDS written as  $r : s$  correspond to  $s/(r + s)$ . A number which can be expressed as a ratio of INTEGERS is called a RATIONAL NUMBER.

see also DENOMINATOR, FRACTION, NUMERATOR, ODDS, QUOTIENT, RATIONAL NUMBER

### Ratio Distribution

Given two distributions  $Y$  and  $X$  with joint probability density function  $f(x, y)$ , let  $U = Y/X$  be the ratio distribution. Then the distribution function of  $u$  is

$$\begin{aligned} D(u) &= P(U \leq u) \\ &= P(Y \leq uX | X > 0) + P(Y \geq uX | X < 0) \\ &= \int_0^\infty \int_0^{ux} f(x, y) dy dx + \int_{-\infty}^0 \int_{ux}^0 f(x, y) dy dx. \end{aligned} \quad (1)$$

The probability function is then

$$\begin{aligned} P(u) &= D'(u) = \int_0^\infty xf(x, ux) dx - \int_{-\infty}^0 xf(x, ux) dx \\ &= \int_{-\infty}^\infty |x|f(x, ux) dx. \end{aligned} \quad (2)$$

For variates with a standard NORMAL DISTRIBUTION, the ratio distribution is a CAUCHY DISTRIBUTION. For a UNIFORM DISTRIBUTION

$$f(x, y) = \begin{cases} 1 & \text{for } x, y \in [0, 1] \\ 0 & \text{otherwise,} \end{cases} \quad (3)$$

$$P(u) = \begin{cases} 0 & u < 0 \\ \int_0^1 x dx = [\frac{1}{2}x^2] = \frac{1}{2} & \text{for } 0 \leq u \leq 1 \\ \int_0^{1/u} x dx = [\frac{1}{2}x^2]_0^{1/u} = \frac{1}{2u^2} & \text{for } u > 1. \end{cases} \quad (4)$$

see also CAUCHY DISTRIBUTION

### Ratio Test

Let  $u_k$  be a SERIES with POSITIVE terms and suppose

$$\rho \equiv \lim_{k \rightarrow \infty} \frac{u_{k+1}}{u_k}.$$

Then

1. If  $\rho < 1$ , the SERIES CONVERGES.
2. If  $\rho > 1$  or  $\rho = \infty$ , the SERIES DIVERGES.
3. If  $\rho = 1$ , the SERIES may CONVERGE or DIVERGE.

The test is also called the CAUCHY RATIO TEST or D'ALEMBERT RATIO TEST.

see also CONVERGENCE TESTS

### Rational Approximation

If  $r$  is any number and  $n$  is any INTEGER, then there is a RATIONAL NUMBER  $m/n$  for which

$$0 \leq r - \frac{m}{n} < \frac{1}{n}. \quad (1)$$

If  $r$  is IRRATIONAL and  $k$  is any WHOLE NUMBER, there is a FRACTION  $m/n$  with  $n \leq k$  and for which

$$0 \leq r - \frac{m}{n} < \frac{1}{nk}. \quad (2)$$

Furthermore, there are an infinite number of FRACTIONS  $m/n$  for which

$$0 \leq r - \frac{m}{n} < \frac{1}{n^2}. \quad (3)$$

Hurwitz has shown that for an IRRATIONAL NUMBER  $\zeta$

$$\left| \zeta - \frac{h}{k} \right| < \frac{1}{ck^2}, \quad (4)$$

there are infinitely RATIONAL NUMBERS  $h/k$  if  $0 < c \leq \sqrt{5}$ , but if  $c > \sqrt{5}$ , there are some  $\zeta$  for which this approximation holds for only finitely many  $h/k$ .

**Rational Canonical Form**

There is an invertible matrix  $Q$  such that

$$Q^{-1}TQ = \text{diag}[L(\psi_1), L(\psi_2), \dots, L(\psi_s)],$$

where  $L(f)$  is the companion MATRIX for any MONIC POLYNOMIAL

$$f(\lambda) = f_0 + f_1\lambda + \dots + f_n\lambda^n$$

with  $f_n = 1$ . The POLYNOMIALS  $\psi_i$  are called the “invariant factors” of  $T$ , and satisfy  $\psi_{i+1}|\psi_i$  for  $i = s - 1, \dots, 1$  (Hartwig 1996).

**Rational Cuboid**

see EULER BRICK

**Rational Distances**

It is possible to find six points in the PLANE, no three on a LINE and no four on a CIRCLE (i.e., none of which are COLLINEAR or CONCYCLIC), such that all the mutual distances are RATIONAL. An example is illustrated by Guy (1994, p. 185).

It is not known if a TRIANGLE with INTEGER sides, MEDIANS, and AREA exists (although there are incorrect PROOFS of the impossibility in the literature). However, R. L. Rathbun, A. Kemnitz, and R. H. Buchholz have showed that there are infinitely many triangles with RATIONAL sides (HERONIAN TRIANGLES) with *two* RATIONAL MEDIANS (Guy 1994, p. 188).

**Rational Domain**

see FIELD

**Rational Double Point**

There are nine possible types of ISOLATED SINGULARITIES on a CUBIC SURFACE, eight of them rational double points. Each type of ISOLATED SINGULARITY has an associated normal form and COXETER-DYNKIN DIAGRAM ( $A_1, A_2, A_3, A_4, A_5, D_4, D_5, E_6$  and  $\tilde{E}_6$ ).

The eight types of rational double points (the  $\tilde{E}_6$  type being the one excluded) can occur in only 20 combinations on a CUBIC SURFACE (of which Fischer 1986 gives 19):  $A_1, 2A_1, 3A_1, 4A_1, A_2, (A_2, A_1), 2A_2, (2A_2, A_1), 3A_2, A_3, (A_3, A_1), (A_3, 2A_1), A_4, (A_4, A_1), A_5, (A_5, A_1), D_4, D_5$ , and  $E_6$  (Looijenga 1978, Bruce and Wall 1979, Fischer 1986).

In particular, on a CUBIC SURFACE, precisely those configurations of rational double points occur for which the disjoint union of the COXETER-DYNKIN DIAGRAM is a SUBGRAPH of the COXETER-DYNKIN DIAGRAM  $\tilde{E}_6$ . Also, a surface specializes to a more complicated one precisely when its graph is contained in the graph of the other one (Fischer 1986).

see also COXETER-DYNKIN DIAGRAM, CUBIC SURFACE, ISOLATED SINGULARITY

**Rational Function**

A quotient of two polynomials  $P(z)$  and  $Q(z)$ ,

$$R(z) \equiv \frac{P(z)}{Q(z)},$$

is called a rational function. More generally, if  $P$  and  $Q$  are POLYNOMIALS in multiple variables, their quotient is a rational function.

see also ABEL’S CURVE THEOREM, CLOSED FORM, FUNDAMENTAL THEOREM OF SYMMETRIC FUNCTIONS, QUOTIENT-DIFFERENCE ALGORITHM, RATIONAL INTEGER, RATIONAL NUMBER, RIEMANN CURVE THEOREM

**Rational Integer**

A synonym for INTEGER. The word “rational” is sometimes used for emphasis to distinguish it from other types of “integers” such as CYCLOTOMIC INTEGERS, EISENSTEIN INTEGERS, and GAUSSIAN INTEGERS.

see also CYCLOTOMIC INTEGER, EISENSTEIN INTEGER, GAUSSIAN INTEGER, INTEGER, RATIONAL NUMBER

References

Hardy, G. H. and Wright, E. M. *An Introduction to the Theory of Numbers*, 5th ed. Oxford, England: Clarendon Press, p. 1, 1979.

**Rational Number**

A number that can be expressed as a FRACTION  $p/q$  where  $p$  and  $q$  are INTEGERS, is called a rational number with NUMERATOR  $p$  and DENOMINATOR  $q$ . Numbers which are not rational are called IRRATIONAL NUMBERS. Any rational number is trivially also an ALGEBRAIC NUMBER.

For  $a$ ,  $b$ , and  $c$  any different rational numbers, then

$$\frac{1}{(a-b)^2} + \frac{1}{(b-c)^2} + \frac{1}{(c-a)^2}$$

is the SQUARE of a rational number (Honsberger 1991). The probability that a random rational number has an EVEN DENOMINATOR is  $1/3$  (Beeler *et al.* 1972, Item 54).

see also ALGEBRAIC INTEGER, ALGEBRAIC NUMBER, ANOMALOUS CANCELLATION, DENOMINATOR, DIRICHLET FUNCTION, FRACTION, INTEGER, IRRATIONAL NUMBER, NUMERATOR, QUOTIENT, TRANSCENDENTAL NUMBER

References

Beeler, M.; Gosper, R. W.; and Schroepfel, R. *HAKMEM*. Cambridge, MA: MIT Artificial Intelligence Laboratory, Memo AIM-239, Feb. 1972.

Courant, R. and Robbins, H. "The Rational Numbers." §2.1 in *What is Mathematics?: An Elementary Approach to Ideas and Methods*, 2nd ed. Oxford, England: Oxford University Press, pp. 52–58, 1996.

Honsberger, R. *More Mathematical Morsels*. Washington, DC: Math. Assoc. Amer., pp. 52–53, 1991.

**Rational Point**

A  $K$ -rational point is a point  $(X, Y)$  on an ALGEBRAIC CURVE, where  $X$  and  $Y$  are in a FIELD  $K$ .

The rational point may also be a POINT AT INFINITY. For example, take the ELLIPTIC CURVE

$$Y^2 = X^3 + X + 42$$

and homogenize it by introducing a third variable  $Z$  so that each term has degree 3 as follows:

$$ZY^2 = X^3 + XZ^2 + 42Z^3.$$

Now, find the points at infinity by setting  $Z = 0$ , obtaining

$$0 = X^3.$$

Solving gives  $X = 0$ ,  $Y$  equal to any value, and (by definition)  $Z = 0$ . Despite freedom in the choice of  $Y$ , there is only a single POINT AT INFINITY because the two triples  $(X_1, Y_1, Z_1)$ ,  $(X_2, Y_2, Z_2)$  are considered to be equivalent (or identified) only if one is a scalar

multiple of the other. Here,  $(0, 0, 0)$  is not considered to be a valid point. The triples  $(a, b, 1)$  correspond to the ordinary points  $(a, b)$ , and the triples  $(a, b, 0)$  correspond to the POINTS AT INFINITY, usually called the LINE AT INFINITY.

The rational points on ELLIPTIC CURVES over the GALOIS FIELD  $GF(q)$  are 5, 7, 9, 10, 13, 14, 16, ... (Sloane's A005523).

see also ELLIPTIC CURVE, LINE AT INFINITY, POINT AT INFINITY

References

Sloane, N. J. A. Sequence A005523/M3757 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Rational Quadrilateral**

A rational quadrilateral is a QUADRILATERAL for which the sides, DIAGONALS, and AREA are RATIONAL. The simplest case has sides  $a = 52$ ,  $b = 25$ ,  $c = 39$ , and  $d = 60$  and DIAGONALS of length  $p = 63$  and  $q = 56$ .

see also AREA, DIAGONAL (POLYGON), RATIONAL QUADRILATERAL

**Rational Triangle**

A rational triangle is a TRIANGLE all of whose sides are RATIONAL NUMBERS and all of whose ANGLES are RATIONAL numbers of DEGREES. The only such triangle is the EQUILATERAL TRIANGLE (Conway and Guy 1996).

see also EQUILATERAL TRIANGLE, FERMAT'S RIGHT TRIANGLE THEOREM, RIGHT TRIANGLE

References

Conway, J. H. and Guy, R. K. "The Only Rational Triangle." In *The Book of Numbers*. New York: Springer-Verlag, pp. 201 and 228–239, 1996.

**RATS Sequence**

A sequence produced by the instructions "reverse, add, then sort the digits," where zeros are suppressed. For example, after 668 we get

$$668 + 866 = 1534,$$

so the next term is 1345. Applied to 1, the sequence gives 1, 2, 4, 8, 16, 77, 145, 668, 1345, 6677, 13444, 55778, ... (Sloane's A004000)

see also 196-ALGORITHM, KAPREKAR ROUTINE, REVERSAL, SORT-THEN-ADD SEQUENCE

References

Sloane, N. J. A. Sequence A004000/M1137 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Ray**

A VECTOR  $\overrightarrow{AB}$  from a point  $A$  to a point  $B$ . In GEOMETRY, a ray is usually taken as a half-infinite LINE with one of the two points  $A$  and  $B$  taken to be at INFINITY.

see also LINE, VECTOR

## Rayleigh Distribution

The distribution with PROBABILITY FUNCTION

$$P(r) = \frac{r e^{-r^2/2s^2}}{s^2} \quad (1)$$

for  $r \in [0, \infty)$ . The MOMENTS about 0 are given by

$$\begin{aligned} \mu'_m &\equiv \int_0^\infty r^m P(r) dr = s^{-2} \int_0^\infty r^{m+1} e^{-r^2/2s^2} dr \\ &= s^{-2} I_{m+1} \left( \frac{1}{2s^2} \right), \end{aligned} \quad (2)$$

where  $I(x)$  is a GAUSSIAN INTEGRAL. The first few of these are

$$I_1(a^{-1}) = \frac{1}{2}a \quad (3)$$

$$I_2(a^{-1}) = \frac{1}{4}a\sqrt{a\pi} \quad (4)$$

$$I_3(a^{-1}) = \frac{1}{2}a^2 \quad (5)$$

$$I_4(a^{-1}) = \frac{3}{8}a^2\sqrt{a\pi} \quad (6)$$

$$I_5(a^{-1}) = a^3, \quad (7)$$

so

$$\mu'_0 = s^{-2} \frac{1}{2} (2s^2) = 1 \quad (8)$$

$$\mu'_1 = s^{-2} \frac{1}{4} (2s^2) \sqrt{2s^2\pi} = \frac{1}{2} s \sqrt{2\pi} = s \sqrt{\frac{\pi}{2}} \quad (9)$$

$$\mu'_2 = s^{-2} \frac{1}{2} (2s^2)^2 = 2s^2 \quad (10)$$

$$\mu'_3 = s^{-2} \frac{3}{8} (2s^2)^2 \sqrt{2s^2\pi} = \frac{3}{2} s^3 \sqrt{2\pi} = 3s^3 \sqrt{\frac{\pi}{2}} \quad (11)$$

$$\mu'_4 = s^{-2} (2s^2)^3 = 8s^4. \quad (12)$$

The MOMENTS about the MEAN are

$$\mu_2 = \mu'_2 - (\mu'_1)^2 = \frac{4 - \pi}{2} s^2 \quad (13)$$

$$\mu_3 = \mu'_3 - 3\mu'_2\mu'_1 + 2(\mu'_1)^3 = \sqrt{\frac{\pi}{2}} (\pi - 3) s^3 \quad (14)$$

$$\begin{aligned} \mu_4 &= \mu'_4 - 4\mu'_3\mu'_1 + 6\mu'_2(\mu'_1)^2 - 3(\mu'_1)^4 \\ &= \frac{32 - 3\pi^2}{4} s^4, \end{aligned} \quad (15)$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \mu'_1 = s \sqrt{\frac{\pi}{2}} \quad (16)$$

$$\sigma^2 = \mu_2 = \frac{4 - \pi}{2} s^2 \quad (17)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = \frac{2(\pi - 3)\sqrt{\pi}}{(4 - \pi)^{3/2}} \quad (18)$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = \frac{2(-3\pi^2 + 12\pi - 8)}{(\pi - 4)^2}. \quad (19)$$

## Rayleigh Differential Equation

$$y'' - \mu(1 - \frac{1}{3}y'^2)y' + y = 0,$$

where  $\mu > 0$ . Differentiating and setting  $y = y'$  gives the VAN DER POL EQUATION.

see also VAN DER POL EQUATION

## Rayleigh's Formulas

The formulas

$$j_n(z) = z^n \left( -\frac{1}{z} \frac{d}{dz} \right)^n \frac{\sin z}{z}$$

$$y_n(z) = -z^n \left( -\frac{1}{z} \frac{d}{dz} \right)^n \frac{\cos z}{z}$$

for  $n = 0, 1, 2, \dots$ , where  $j_n(z)$  is a SPHERICAL BESSEL FUNCTION OF THE FIRST KIND and  $y_n(z)$  is a SPHERICAL BESSEL FUNCTION OF THE SECOND KIND.

## Rayleigh-Ritz Variational Technique

A technique for computing EIGENFUNCTIONS and EIGENVALUES. It proceeds by requiring

$$J = \int_a^b [p(x)y_x^2 - q(x)y^2] dx \quad (1)$$

to have a STATIONARY VALUE subject to the normalization condition

$$\int_a^b y^2 w(x) dx = 1 \quad (2)$$

and the boundary conditions

$$py_x y|_a^b = 0. \quad (3)$$

This leads to the STURM-LIOUVILLE EQUATION

$$\frac{d}{dx} \left( p \frac{dy}{dx} \right) + qy + \lambda wy = 0, \quad (4)$$

which gives the stationary values of

$$F[y(x)] = \frac{\int_a^b (py_x^2 - qy^2) dx}{\int_a^b y^2 w dx} \quad (5)$$

as

$$F[y_n(x)] = \lambda_n, \quad (6)$$

where  $\lambda_n$  are the EIGENVALUES corresponding to the EIGENFUNCTION  $y_n$ .

**Rayleigh's Theorem**

see PARSEVAL'S THEOREM

**Re-Entrant Circuit**

A CYCLE in a GRAPH which terminates at the starting point.

see also CYCLE (GRAPH), EULERIAN CIRCUIT, HAMILTONIAN CYCLE

**Real Analysis**

That portion of mathematics dealing with functions of real variables. While this includes some portions of TOPOLOGY, it is most commonly used to distinguish that portion of CALCULUS dealing with real as opposed to COMPLEX NUMBERS.

**Real Axis**

see REAL LINE

**Real Function**

A FUNCTION whose RANGE is in the REAL NUMBERS is said to be a real function.

see also COMPLEX FUNCTION, SCALAR FUNCTION, VECTOR FUNCTION

**Real Line**

A LINE with a fixed scale so that every REAL NUMBER corresponds to a unique POINT on the LINE. The generalization of the real line to 2-D is called the COMPLEX PLANE.

see also ABSCISSA, COMPLEX PLANE

**References**

Courant, R. and Robbins, H. *What is Mathematics?: An Elementary Approach to Ideas and Methods*, 2nd ed. Oxford, England: Oxford University Press, p. 57, 1996.

**Real Matrix**

A MATRIX whose elements consist entirely of REAL NUMBERS.

**Real Number**

The set of all RATIONAL and IRRATIONAL numbers is called the real numbers, or simply the "reals," and denoted  $\mathbb{R}$ . The set of real numbers is also called the CONTINUUM, denoted  $C$ .

The real numbers can be extended with the addition of the IMAGINARY NUMBER  $i$ , equal to  $\sqrt{-1}$ . Numbers of the form  $x + iy$ , where  $x$  and  $y$  are both real, are then called COMPLEX NUMBERS. Another extension which includes both the real numbers and the infinite ORDINAL NUMBERS of Georg Cantor is the SURREAL NUMBERS.

Pick two real numbers  $x$  and  $y$  at random in  $(0, 1)$  with a UNIFORM DISTRIBUTION. What is the PROBABILITY  $P_{\text{even}}$  that  $[x/y]$ , where  $[r]$  denotes NINT, the nearest INTEGER to  $r$ , is EVEN? The answer may be found as follows (Putnam Exam).

$$P\left(a < \frac{x}{y} < b\right) = \begin{cases} P(ay < x < by) \\ P\left(\frac{x}{b} < y < \frac{x}{a}\right) \end{cases}$$

$$= \begin{cases} \int_0^1 \int_{ay}^{by} dx dy = \frac{1}{2}(b-a) & \text{for } 0 \leq a < b < 1 \\ \int_0^1 \int_{x/b}^{x/a} dy dx = \frac{1}{2a} - \frac{1}{2b} & \text{for } 1 < a < b \end{cases} \quad (1)$$

$$P_{\text{even}} = P\left(0 < \frac{x}{y} < \frac{1}{2}\right) + \sum_{n=1}^{\infty} P\left(2n - \frac{1}{2} < \frac{x}{y} < 2n + \frac{1}{2}\right)$$

$$= \frac{1}{2}\left(\frac{1}{2} - 0\right) + \sum_{n=1}^{\infty} \left[ \frac{1}{2(2n - \frac{1}{2})} - \frac{1}{2(2n + \frac{1}{2})} \right]$$

$$= \frac{1}{4} + \sum_{n=1}^{\infty} \left( \frac{1}{4n-1} - \frac{1}{4n+1} \right)$$

$$= \frac{1}{4} + \left( \frac{1}{3} - \frac{1}{5} + \frac{1}{7} - \frac{1}{9} + \dots \right) = \frac{1}{4} + (1 - \tan^{-1} 1)$$

$$= \frac{5}{4} - \frac{\pi}{4} = \frac{1}{4}(5 - \pi) \approx 46.460\%. \quad (2)$$

Plouffe's "Inverse Symbolic Calculator" includes a huge database of 54 million real numbers which are algebraically related to fundamental mathematical constants and functions.

**Real Part**

The real part  $\Re$  of a COMPLEX NUMBER  $z = x + iy$  is the REAL NUMBER *not* multiplying  $i$ , so  $\Re[x + iy] = x$ . In terms of  $z$  itself,

$$\Re[z] = \frac{1}{2}(z + z^*),$$

where  $z^*$  is the COMPLEX CONJUGATE of  $z$ .

see also ABSOLUTE SQUARE, COMPLEX CONJUGATE, IMAGINARY PART

**Real Polynomial**

A POLYNOMIAL having only REAL NUMBERS as COEFFICIENTS.

see also POLYNOMIAL

**Real Projective Plane**

The closed topological MANIFOLD, denoted  $\mathbb{R}P^2$ , which is obtained by projecting the points of a plane  $E$  from a fixed point  $P$  (not on the plane), with the addition of the LINE AT INFINITY, is called the real projective plane. There is then a one-to-one correspondence between points in  $E$  and lines through  $P$ . Since each line through  $P$  intersects the sphere  $\mathbb{S}^2$  centered at  $P$  and tangent to  $E$  in two ANTIPODAL POINTS,  $\mathbb{R}P^2$  can be described as a QUOTIENT SPACE of  $\mathbb{S}^2$  by identifying any two such points. The real projective plane is a NONORIENTABLE SURFACE.

The BOY SURFACE, CROSS-CAP, and ROMAN SURFACE are all homeomorphic to the real projective plane and, because  $\mathbb{R}P^2$  is nonorientable, these surfaces contain self-intersections (Kuiper 1961, Pinkall 1986).

see also BOY SURFACE, CROSS-CAP, NONORIENTABLE SURFACE, PROJECTIVE PLANE, ROMAN SURFACE

**Real Quadratic Field**

A QUADRATIC FIELD  $\mathbb{Q}(\sqrt{D})$  with  $D > 0$ .

see also QUADRATIC FIELD

**Realizer**

A SET of  $R$  of LINEAR EXTENSIONS of a POSET  $P = (X, \leq)$  is a realizer of  $P$  (and is said to realize  $P$ ) provided that for all  $x, y \in X$ ,  $x \leq y$  IFF  $x$  is below  $y$  in every member of  $R$ .

see also DOMINANCE, LINEAR EXTENSION, PARTIALLY ORDERED SET, POSET DIMENSION

**Rearrangement Theorem**

Each row and each column in the GROUP multiplication table lists each of the GROUP elements once and only once. From this, it follows that no two elements may be in the identical location in two rows or two columns. Thus, each row and each column is a rearranged list of the GROUP elements. Stated otherwise, given a GROUP

of  $n$  distinct elements  $(I, a, b, c, \dots, n)$ , the set of products  $(aI, a^2, ab, ac, \dots, an)$  reproduces the  $n$  original distinct elements in a new order.

see also GROUP

**Reciprocal**

The reciprocal of a REAL or COMPLEX NUMBER  $z$  is its MULTIPLICATIVE INVERSE  $1/z$ . The reciprocal of a COMPLEX NUMBER  $z = x + iy$  is given by

$$\frac{1}{x + iy} = \frac{x - iy}{x^2 + y^2} = \frac{x}{x^2 + y^2} - \frac{y}{x^2 + y^2}i.$$

**Reciprocal Difference**

The reciprocal differences are closely related to the DIVIDED DIFFERENCE. The first few are explicitly given by

$$\rho(x_0, x_1) = \frac{x_0 - x_1}{f_0 - f_1} \quad (1)$$

$$\rho_2(x_0, x_1, x_2) = \frac{x_0 - x_2}{\rho(x_0, x_1) - \rho(x_1, x_2)} + f_1 \quad (2)$$

$$\rho_3(x_0, x_1, x_2, x_3) = \frac{x_0 - x_3}{\rho_2(x_0, x_1, x_2) - \rho_2(x_1, x_2, x_3)} + \rho(x_1, x_2) \quad (3)$$

$$\begin{aligned} \rho_n(x_0, x_1, \dots, x_n) \\ = \frac{x_0 - x_n}{\rho_{n-1}(x_0, \dots, x_{n-1}) - \rho_{n-1}(x_1, \dots, x_n)} \\ + \rho_{n-2}(x_1, \dots, x_{n-1}). \end{aligned} \quad (4)$$

**Reciprocity Theorem**

If there exists a RATIONAL INTEGER  $x$  such that, when  $n$ ,  $p$ , and  $q$  are POSITIVE INTEGERS,

$$x^n \equiv q \pmod{p},$$

then  $q$  is the  $n$ -adic residue of  $p$ , i.e.,  $q$  is an  $n$ -adic residue of  $p$  IFF  $x^n \equiv q \pmod{p}$  is solvable for  $x$ .

The first case to be considered was  $n = 2$  (the QUADRATIC RECIPROCITY THEOREM), of which Gauss gave the first correct proof. Gauss also solved the case  $n = 3$  (CUBIC RECIPROCITY THEOREM) using INTEGERS of the form  $a + b\rho$ , when  $\rho$  is a root of  $x^2 + x + 1 = 0$  and  $a$ ,  $b$  are rational INTEGERS. Gauss stated the case  $n = 4$  (QUARTIC RECIPROCITY THEOREM) using the GAUSSIAN INTEGERS.

Proof of  $n$ -adic reciprocity for PRIME  $n$  was given by Eisenstein in 1844–50 and by Kummer in 1850–61. In the 1920s, Artin formulated ARTIN'S RECIPROCITY THEOREM, a general reciprocity law for all orders.

see also ARTIN RECIPROCITY, CUBIC RECIPROCITY THEOREM, LANGLANDS RECIPROCITY, QUADRATIC RECIPROCITY THEOREM, QUARTIC RECIPROCITY THEOREM, ROOK RECIPROCITY THEOREM

**Rectangle**

A closed planar QUADRILATERAL with opposite sides of equal lengths  $a$  and  $b$ , and with four RIGHT ANGLES. The AREA of the rectangle is

$$A = ab,$$

and its DIAGONALS are of length

$$p, q = \sqrt{a^2 + b^2}.$$

A SQUARE is a degenerate rectangle with  $a = b$ .

see also GOLDEN RECTANGLE, PERFECT RECTANGLE, SQUARE

Eppstein, D. "Rectilinear Geometry." <http://www.ics.uci.edu/~eppstein/junkyard/rect.html>.

**Rectangle Function**

The rectangle function  $\Pi(x)$  is a function which is 0 outside the interval  $[-1, 1]$  and unity inside it. It is also called the GATE FUNCTION, PULSE FUNCTION, or WINDOW FUNCTION, and is defined by

$$\Pi(x) \equiv \begin{cases} 0 & \text{for } |x| > \frac{1}{2} \\ \frac{1}{2} & \text{for } |x| = \frac{1}{2} \\ 1 & \text{for } |x| < \frac{1}{2}. \end{cases} \quad (1)$$

The function  $f(x) = h\Pi((x - c)/b)$  has height  $h$ , center  $c$ , and full-width  $b$ . Identities satisfied by the rectangle function include

$$\Pi(x) = H(x + \frac{1}{2}) - H(x - \frac{1}{2}) \quad (2)$$

$$= H(\frac{1}{2} + x) + H(\frac{1}{2} - x) - 1 \quad (3)$$

$$= H(\frac{1}{4} - x^2) \quad (4)$$

$$= \frac{1}{2}[\text{sgn}(x + \frac{1}{2}) - \text{sgn}(x - \frac{1}{2})], \quad (5)$$

where  $H(x)$  is the HEAVISIDE STEP FUNCTION. The FOURIER TRANSFORM of the rectangle function is given by

$$\mathcal{F}[\Pi(x)] = \int_{-\infty}^{\infty} e^{-2\pi i k x} \Pi(x) dx = \text{sinc}(\pi k), \quad (6)$$

where  $\text{sinc}(x)$  is the SINC FUNCTION.

see also FOURIER TRANSFORM—RECTANGLE FUNCTION, HEAVISIDE STEP FUNCTION, RAMP FUNCTION

**Rectangle Squaring**

Given a RECTANGLE  $\square BCDE$ , draw  $EF = DE$  on an extension of  $BE$ . Bisect  $BF$  and call the MIDPOINT  $G$ . Now draw a SEMICIRCLE centered at  $G$ , and construct the extension of  $ED$  which passes through the SEMICIRCLE at  $H$ . Then  $\square EKLH$  has the same AREA as  $\square BCDE$ . This can be shown as follows:

$$\begin{aligned} A(\square BCDE) &= BE \cdot ED = BE \cdot EF \\ &= (a + b)(a - b) = a^2 - b^2 = c^2. \end{aligned}$$

**Rectangular Coordinates**

see CARTESIAN COORDINATES

**Rectangular Distribution**

see UNIFORM DISTRIBUTION

**Rectangular Hyperbola**

A RIGHT HYPERBOLA of the special form

$$xy = ab,$$

so that the ASYMPTOTES are the lines  $x = 0$  and  $y = 0$ . The rectangular hyperbola is sometimes also called an EQUILATERAL HYPERBOLA.

see also HYPERBOLA, RIGHT HYPERBOLA

**References**

Courant, R. and Robbins, H. *What is Mathematics?: An Elementary Approach to Ideas and Methods*, 2nd ed. Oxford, England: Oxford University Press, pp. 76–77, 1996.

**Rectangular Parallelepiped**

A closed box composed of 3 pairs of rectangular faces placed opposite each other and joined at RIGHT ANGLES to each other. This PARALLELEPIPED therefore corresponds to a rectangular “box.” If the lengths of the sides are denoted  $a$ ,  $b$ , and  $c$ , then the VOLUME is

$$V = abc, \quad (1)$$

the total SURFACE AREA is

$$A = 2(ab + bc + ca), \quad (2)$$

and the length of the “space” DIAGONAL is

$$d_{abc} = \sqrt{a^2 + b^2 + c^2}. \quad (3)$$

If  $a = b = c$ , then the rectangular parallelepiped is a CUBE.

**Rectifiable Current**

The space of currents arising from rectifiable sets by integrating a differential form is called the space of 2-D rectifiable currents. For  $C$  a closed bounded rectifiable curve of a number of components in  $\mathbb{R}^3$ ,  $C$  bounds a rectifiable current of least AREA. The theory of rectifiable currents generalizes to  $m$ -D surfaces in  $\mathbb{R}^n$ .

see also INTEGRAL CURRENT, REGULARITY THEOREM

**References**

Morgan, F. “What is a Surface?” *Amer. Math. Monthly* **103**, 369–376, 1996.

**Rectifiable Set**

The rectifiable sets include the image of any LIPSCHITZ FUNCTION  $f$  from planar domains into  $\mathbb{R}^3$ . The full set is obtained by allowing arbitrary measurable subsets of countable unions of such images of Lipschitz functions as long as the total AREA remains finite. Rectifiable sets have an “approximate” tangent plane at almost every point.

**References**

Morgan, F. “What is a Surface?” *Amer. Math. Monthly* **103**, 369–376, 1996.

**Rectification**

Rectification is the determination of the length of a curve.

see also QUADRABLE, SQUARING

**Rectifying Latitude**

An AUXILIARY LATITUDE which gives a sphere having correct distances along the meridians. It is denoted  $\mu$  (or  $\omega$ ) and is given by

$$\mu = \frac{\pi M}{2M_p}. \quad (1)$$

$M_p$  is evaluated for  $M$  at the north pole ( $\phi = 90^\circ$ ), and  $M$  is given by

$$\begin{aligned} M &= a(1 - e^2) \int_0^\phi \frac{d\phi}{(1 - e^2 \sin^2 \phi)^{3/2}} \\ &= a \left[ \int_0^\phi \sqrt{1 - e^2 \sin^2 \phi} d\phi - \frac{e^2 \sin \phi \cos \phi}{\sqrt{1 - e^2 \sin^2 \phi}} \right]. \end{aligned} \quad (2)$$

A series for  $M$  is

$$\begin{aligned} M &= a \left[ \left( 1 - \frac{1}{4}e^2 - \frac{3}{64}e^4 - \frac{5}{256}e^6 - \dots \right) \phi \right. \\ &\quad - \left( \frac{3}{8}e^2 + \frac{32}{32}e^4 + \frac{45}{1024}e^6 + \dots \right) \sin(2\phi) \\ &\quad + \left( \frac{15}{256}e^4 + \frac{45}{1024}e^6 + \dots \right) \sin(4\phi) \\ &\quad \left. - \left( \frac{35}{3072}e^6 + \dots \right) \sin(6\phi) + \dots \right], \end{aligned} \quad (3)$$

and a series for  $\mu$  is

$$\begin{aligned}\mu = & \phi - \left(\frac{3}{2}e_1 - \frac{9}{16}e_1^3 + \dots\right)\sin(2\phi) \\ & + \left(\frac{15}{16}e_1^2 - \frac{15}{32}e_1^4 + \dots\right)\sin(4\phi) \\ & - \left(\frac{35}{48}e_1^3 - \dots\right)\sin(6\phi) + \left(\frac{315}{512}e_1^4 - \dots\right)\sin(8\phi) + \dots,\end{aligned}\quad (4)$$

where

$$e_1 = \frac{1 - \sqrt{1 - e^2}}{1 + \sqrt{1 - e^2}}. \quad (5)$$

The inverse formula is

$$\begin{aligned}\phi = & \mu + \left(\frac{3}{2}e_1 - \frac{27}{32}e_1^3 + \dots\right)\sin(2\mu) \\ & + \left(\frac{21}{16}e_1^2 - \frac{55}{32}e_1^4 + \dots\right)\sin(4\mu) \\ & + \left(\frac{151}{96}e_1^3 - \dots\right)\sin(6\mu) \\ & + \left(\frac{1097}{512}e_1^4 - \dots\right)\sin(8\mu) + \dots\end{aligned}\quad (6)$$

#### Rectifying Plane

The PLANE spanned by the TANGENT VECTOR **T** and BINORMAL VECTOR **B**.

see also BINORMAL VECTOR, TANGENT VECTOR

#### Recurrence Relation

A mathematical relationship expressing  $f_n$  as some combination of  $f_i$  with  $i < n$ . The solutions to linear recurrence can be computed straightforwardly, but QUADRATIC RECURRENCES are not so well understood. The sequence generated by a recurrence relation is called a RECURRENCE SEQUENCE. Perhaps the most famous example of a recurrence relation is the one defining the FIBONACCI NUMBERS,

$$F_n = F_{n-2} + F_{n-1}$$

for  $n \geq 3$  and with  $F_1 = F_2 = 1$ .

see also ARGUMENT ADDITION RELATION, ARGUMENT MULTIPLICATION RELATION, CLENSHAW RECURRENCE FORMULA, QUADRATIC RECURRENCE, RECURRENCE SEQUENCE, REFLECTION RELATION, TRANSLATION RELATION

#### References

- Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Recurrence Relations and Clenshaw's Recurrence Formula." §5.5 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 172-178, 1992.

#### Recurrence Sequence

A sequence of numbers generated by a RECURRENCE RELATION is called a recurrence sequence. Perhaps the most famous recurrence sequence is the FIBONACCI NUMBERS.

If a sequence  $\{x_n\}$  with  $x_1 = x_2 = 1$  is described by a two-term linear recurrence relation of the form

$$x_n = Ax_{n-1} + Bx_{n-2} \quad (1)$$

for  $n \geq 3$  and  $A$  and  $B$  constants, then the closed form for  $x_n$  is given by

$$x_n = \frac{\alpha^n - \beta^n}{\alpha - \beta} \quad (2)$$

where  $\alpha$  and  $\beta$  are the ROOTS of the QUADRATIC EQUATION

$$x^2 - Ax - B = 0, \quad (3)$$

$$\alpha = \frac{1}{2}(A + \sqrt{A^2 + 4B}) \quad (4)$$

$$\beta = \frac{1}{2}(A - \sqrt{A^2 + 4B}). \quad (5)$$

The general second-order linear recurrence

$$x_n = Ax_{n-1} + Bx_{n-2} \quad (6)$$

for constants  $A$  and  $B$  with arbitrary  $x_1$  and  $x_2$  has terms

$$\begin{aligned}x_1 &= x_1 \\ x_2 &= x_2 \\ x_3 &= Bx_1 + Ax_2 \\ x_4 &= Bx_2 + ABx_1 + A^2x_2 \\ x_5 &= B^2x_1 + 2ABx_2 + A^2Bx_1 + A^3x_2 \\ x_6 &= B^2x_2 + 2AB^2x_1 + 3A^2Bx_2 + A^3Bx_1 + A^4x_2.\end{aligned}$$

Dropping  $x_1$ ,  $x_2$ , and  $A$ , this can be written

$$\begin{array}{ccccccc}1 & & & & & & \\1 & & & & & & \\B & 1 & & & & & \\B & B & 1 & & & & \\B^2 & 2B & B & 1 & & & \\B^2 & 2B^2 & 3B & B & 1 & & \end{array}$$

which is simply PASCAL'S TRIANGLE on its side. An arbitrary term can therefore be written as

$$x_n = \sum_{k=0}^{n-2} \binom{\lfloor \frac{1}{2}(n+k-2) \rfloor}{k} A^k B^{\lfloor (n-k-1)/2 \rfloor} \times x_1^{[n+k \pmod{2}]} x_2^{[n+k+1 \pmod{2}]} \quad (7)$$

$$\begin{aligned}&= -(Ax_1 - x_2) \sum_{k=0}^{n-2} A^{2k-n+2} B^{-k+n-2} \binom{k}{n-k-2} \\ &+ x_1 \sum_{k=0}^{n-1} A^{2k-n+1} B^{-k+n-1} \binom{k}{n-k-1}.\end{aligned}\quad (8)$$

The general linear third-order recurrence

$$x_n = Ax_{n-1} + Bx_{n-2} + Cx_{n-3} \quad (9)$$

has solution

$$\begin{aligned} x_n = x_1 & \left( \frac{\alpha^{-n}}{A + 2\alpha B + 3\alpha^2 C} + \frac{\beta^{-n}}{A + 2\beta B + 3\beta^2 C} \right. \\ & \left. + \frac{\gamma^{-n}}{A + 2\gamma B + 3\gamma^2 C} \right) \\ & - (Ax_1 - x_2) \left( \frac{\alpha^{1-n}}{A + 2\alpha B + 3\alpha^2 C} + \frac{\beta^{1-n}}{A + 2\beta B + 3\beta^2 C} \right. \\ & \left. + \frac{\gamma^{1-n}}{A + 2\gamma C + 3\gamma^2 C} \right) \\ & - (Bx_1 + Ax_2 - x_3) \left( \frac{\alpha^{2-n}}{A + 2\alpha B + 3\alpha^2 C} \right. \\ & \left. + \frac{\beta^{2-n}}{A + 2\beta B + 3\beta^2 C} + \frac{\gamma^{2-n}}{A + 2\gamma B + 3\gamma^2 C} \right), \quad (10) \end{aligned}$$

where  $\alpha$ ,  $\beta$ , and  $\gamma$  are the roots of the polynomial

$$Cx^3 + Bx^2 + Ax = 1. \quad (11)$$

A QUOTIENT-DIFFERENCE TABLE eventually yields a line of 0s IFF the starting sequence is defined by a linear recurrence relation.

A linear second-order recurrence

$$f_{n+1} = xf_n + yf_{n-1} \quad (12)$$

can be solved rapidly using a "rate doubling,"

$$f_{n+2} = (x^2 + 2y)f_n - y^2 f_{n-2}, \quad (13)$$

"rate tripling"

$$f_{n+3} = (x^3 + 3xy)f_n + y^3 f_{n-3}, \quad (14)$$

or in general, "rate  $k$ -tupling" formula

$$f_{n+k} = p_k f_n + q_k f_{n-k}, \quad (15)$$

where

$$p_0 = 2 \quad (16)$$

$$p_1 = x \quad (17)$$

$$p_k = 2(-y)^{k/2} T_k(x/(2i\sqrt{y})) \quad (18)$$

$$p_{k+1} = xp_k + yp_{k-1} \quad (19)$$

(here,  $T_k(x)$  is a CHEBYSHEV POLYNOMIAL OF THE FIRST KIND) and

$$q_0 = -1 \quad (20)$$

$$q_1 = y \quad (21)$$

$$q_k = -(-y)^k \quad (22)$$

$$q_{k+1} = -yq_k \quad (23)$$

(Beeler *et al.* 1972, Item 14).

Let

$$s(X) = \prod_{i=1}^m (1 - \alpha_i X)^{n_i} = 1 - s_1 X - \dots - s_n X^n, \quad (24)$$

where the generalized POWER sum  $a(h)$  for  $h = 0, 1, \dots$  is given by

$$a(h) = \sum_{i=1}^m A_i(h) \alpha_i^h, \quad (25)$$

with distinct NONZERO roots  $\alpha_i$ , COEFFICIENTS  $A_i(h)$  which are POLYNOMIALS of degree  $n_i - 1$  for POSITIVE INTEGERS  $n_i$ , and  $i \in [1, m]$ . Then the sequence  $\{a_h\}$  with  $a_h = a(h)$  satisfies the RECURRENCE RELATION

$$a_{h+n} = s_1 a_{h+n-1} + \dots + s_n a_h \quad (26)$$

(Meyerson and van der Poorten 1995).

The terms in a general recurrence sequence belong to a finitely generated RING over the INTEGERS, so it is impossible for every RATIONAL NUMBER to occur in any finitely generated recurrence sequence. If a recurrence sequence vanishes infinitely often, then it vanishes on an arithmetic progression with a common difference 1 that depends only on the roots. The number of values that a recurrence sequence can take on infinitely often is bounded by some INTEGER  $l$  that depends only on the roots. There is no recurrence sequence in which each INTEGER occurs infinitely often, or in which every GAUSSIAN INTEGER occurs (Myerson and van der Poorten 1995).

Let  $\mu(n)$  be a bound so that a nondegenerate INTEGER recurrence sequence of order  $n$  takes the value zero at least  $\mu(n)$  times. Then  $\mu(2) = 1$ ,  $\mu(3) = 6$ , and  $\mu(4) \geq 9$  (Myerson and van der Poorten 1995). The maximal case for  $\mu(3)$  is

$$a_{n+3} = 2a_{n+2} - 4a_{n+1} + 4a_n \quad (27)$$

with

$$a_0 = a_1 = 0 \quad (28)$$

$$a_2 = 1. \quad (29)$$

The zeros are

$$a_0 = a_1 = a_4 = a_6 = a_{13} = a_{52} = 0 \quad (30)$$

(Beukers 1991).

**Recurring Digital Invariant**

To define a recurring digital invariant of order  $k$ , compute the sum of the  $k$ th powers of the digits of a number  $n$ . If this number  $n'$  is equal to the original number  $n$ , then  $n = n'$  is called a  $k$ -NARCISSISTIC NUMBER. If not, compute the sums of the  $k$ th powers of the digits of  $n'$ , and so on. If this process eventually leads back to the original number  $n$ , the *smallest number* in the sequence  $\{n, n', n'', \dots\}$  is said to be a  $k$ -recurring digital invariant. For example,

$$\begin{aligned} 55 : 5^3 + 5^3 &= 250 \\ 250 : 2^3 + 5^3 + 0^3 &= 133 \\ 133 : 1^3 + 3^3 + 3^3 &= 55, \end{aligned}$$

so 55 is an order 3 recurring digital invariant. The following table gives recurring digital invariants of orders 2 to 10 (Madachy 1979).

Order	RDIs	Cycle Lengths
2	4	8
3	55, 136, 160, 919	3, 2, 3, 2
4	1138, 2178	7, 2
5	244, 8294, 8299, 9044, 9045, 10933, 24584, 58618, 89883	28, 10, 6, 10, 22, 4, 12, 2, 2

**Recursion**

A recursive process is one in which objects are defined in terms of other objects of the same type. Using some sort of RECURRENCE RELATION, the entire class of objects can then be built up from a few initial values and a small number of rules. The FIBONACCI NUMBERS are most commonly defined recursively. Care, however, must be taken to avoid SELF-RECURSION, in which an object is defined in terms of itself, leading to an infinite nesting.

Péter, R. *Rekursive Funktionen*. Budapest: Akad. Kiado, 1951.

**Recursive Function**

A recursive function is a function generated by (1) ADDITION, (2) MULTIPLICATION, (3) selection of an element from a list, and (4) determination of the truth or falsity of the INEQUALITY  $a < b$  according to the technical rules:

1. If  $F$  and the sequence of functions  $G_1, \dots, G_n$  are recursive, then so is  $F(G_1, \dots, G_n)$ .
2. If  $F$  is a recursive function such that there is an  $x$  for each  $a$  with  $H(a, x) = 0$ , then the smallest  $x$  can be obtained recursively.

A TURING MACHINE is capable of computing recursive functions.

**Red-Black Tree**

An extended BINARY TREE satisfying the following conditions:

1. Every node has two CHILDREN, each colored either red or black.
2. Every LEAF node is colored black.
3. Every red node has both of its CHILDREN colored black.
4. Every path from the ROOT to a LEAF contains the same number (the "black-height") of black nodes.

Let  $n$  be the number of internal nodes of a red-black tree. Then the number of red-black trees for  $n = 1, 2, \dots$  is 2, 2, 3, 8, 14, 20, 35, 64, 122, ... (Sloane's A001131). The number of trees with black roots and red roots are given by Sloane's A001137 and Sloane's A001138, respectively.

Let  $T_h$  be the GENERATING FUNCTION for the number of red-black trees of black-height  $h$  indexed by the number of LEAVES. Then

$$T_{h+1}(x) = [T_h(x)]^2 + [T_h(x)]^4, \quad (1)$$

where  $T_1(x) = x + x^2$ . If  $T(x)$  is the GENERATING FUNCTION for the number of red-black trees, then

$$T(x) = x + x^2 + T(x^2(1+x)^2) \quad (2)$$

(Ruskey). Let  $rb(n)$  be the number of red-black trees with  $n$  LEAVES,  $r(n)$  the number of red-rooted trees, and  $b(n)$  the number of black-rooted trees. All three of the quantities satisfy the RECURRENCE RELATION

$$R(n) = \sum_{n/4 \leq n \leq n/2} \binom{2m}{n-2m} R(m), \quad (3)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT,  $rb(1) = 1$ ,  $rb(2) = 2$  for  $R(n) = rb(n)$ ,  $r(1) = r(3) = 0$ ,  $r(2) = 1$  for  $R(n) = r(n)$ , and  $b(1) = 1$  for  $R(n) = b(n)$  (Ruskey).

#### Red Net

The coloring red of two COMPLETE SUBGRAPHS of  $n/2$  points (for EVEN  $n$ ) in order to generate a BLUE-EMPTY GRAPH.

see also BLUE-EMPTY GRAPH, COMPLETE GRAPH

#### Reduced Amicable Pair

see QUASIAMICABLE PAIR

#### Reduced Fraction

A FRACTION  $a/b$  written in lowest terms, i.e., by dividing NUMERATOR and DENOMINATOR through by their GREATEST COMMON DIVISOR ( $a, b$ ). For example,  $2/3$  is the reduced fraction of  $8/12$ .

see also FRACTION, PROPER FRACTION

#### Reduced Latitude

see PARAMETRIC LATITUDE

#### Reducible Crossing

A crossing in a LINK projection which can be removed by rotating part of the LINK, also called REMOVABLE CROSSING.

see also ALTERNATING KNOT

#### Reducible Representation

see IRREDUCIBLE REPRESENTATION

#### Reducible Matrix

A SQUARE  $n \times n$  matrix  $A = a_{ij}$  is called reducible if the indices  $1, 2, \dots, n$  can be divided into two disjoint nonempty sets  $i_1, i_2, \dots, i_\mu$  and  $j_1, j_2, \dots, j_\nu$  (with  $\mu + \nu = n$ ) such that

$$a_{i_\alpha j_\beta} = 0$$

for  $\alpha = 1, 2, \dots, \mu$  and  $\beta = 1, 2, \dots, \nu$ . A SQUARE MATRIX which is not reducible is said to be IRREDUCIBLE.

### Regular Isotopy

The equivalence of MANIFOLDS under continuous deformation within the embedding space. KNOTS of opposite CHIRALITY have AMBIENT ISOTOPY, but not regular isotopy.

see also AMBIENT ISOTOPY

**Regular Isotopy Invariant**

see BRACKET POLYNOMIAL

**Regular Local Ring**

A regular local ring is a LOCAL RING  $R$  with MAXIMAL IDEAL  $m$  so that  $m$  can be generated with exactly  $d$  elements where  $d$  is the KRULL DIMENSION of the RING  $R$ . Equivalently,  $R$  is regular if the VECTOR SPACE  $m/m^2$  has dimension  $d$ .

see also KRULL DIMENSION, LOCAL RING, REGULAR RING, RING

**References**

Eisenbud, D. *Commutative Algebra with a View Toward Algebraic Geometry*. New York: Springer-Verlag, p. 242, 1995.

**Regular Number**

A number which has a finite DECIMAL expansion. A number which is not regular is said to be nonregular.

see also DECIMAL EXPANSION, REPEATING DECIMAL

**Regular Parameterization**

A parameterization of a SURFACE  $\mathbf{x}(u, v)$  in  $u$  and  $v$  is regular if the TANGENT VECTORS

$$\frac{\partial \mathbf{x}}{\partial u} \quad \text{and} \quad \frac{\partial \mathbf{x}}{\partial v}$$

are always LINEARLY INDEPENDENT.

**Regular Patch**

A regular patch is a PATCH  $\mathbf{x} : U \rightarrow \mathbb{R}^n$  for which the JACOBIAN  $J(\mathbf{x})(u, v)$  has rank 2 for all  $(u, v) \in U$ . A PATCH is said to be regular at a point  $(u_0, v_0) \in U$  providing that its JACOBIAN has rank 2 at  $(u_0, v_0)$ . For example, the points at  $\phi = \pm\pi/2$  in the standard parameterization of the SPHERE  $(\cos \theta \sin \phi, \sin \theta \sin \phi, \cos \phi)$  are not regular.

An example of a PATCH which is regular but not INJECTIVE is the CYLINDER defined parametrically by  $(\cos u, \sin u, v)$  with  $u \in (-\infty, \infty)$  and  $v \in (-2, 2)$ . However, if  $\mathbf{x} : U \rightarrow \mathbb{R}^n$  is an injective regular patch, then  $\mathbf{x}$  maps  $U$  diffeomorphically onto  $\mathbf{x}(U)$ .

**Regular Point**

see ORDINARY POINT

**Regular Polygon**

An  $n$ -sided POLYGON in which the sides are all the same length and are symmetrically placed about a common center. The sum of PERPENDICULARS from any point to the sides of a regular polygon of  $n$  sides is  $n$  times the APOTHEM. Only certain regular polygons are "CONSTRUCTIBLE" with RULER and STRAIGHTEDGE.

$n$	Regular Polygon
3	equilateral triangle
4	square
5	pentagon
6	hexagon
7	heptagon
8	octagon
9	nonagon
10	decagon
12	dodecagon
15	pentadecagon
16	hexadecagon
17	heptadecagon
18	octadecagon
20	icosagon
30	triacontagon

see also CONSTRUCTIBLE POLYGON, GEOMETROGRAPHY, HEPTADECAGON, POLYGON

**References**

Bishop, W. "How to Construct a Regular Polygon." *Amer. Math. Monthly* **85**, 186–188, 1978.

**Regular Polyhedron**

A polyhedron is said to be regular if its FACES and VERTEX FIGURES are REGULAR (not necessarily CONVEX) polygons (Coxeter 1973, p. 16). Using this definition, there are a total of nine regular polyhedra, five being the CONVEX PLATONIC SOLIDS and four being the CONCAVE (stellated) KEPLER-POINSON SOLIDS. However, the term "regular polyhedra" is sometimes used to refer exclusively to the CONVEX PLATONIC SOLIDS.

It can be proven that only nine regular solids (in the Coxeter sense) exist by noting that a possible regular polyhedron must satisfy

$$\cos^2 \left( \frac{\pi}{p} \right) + \cos^2 \left( \frac{\pi}{q} \right) + \cos^2 \left( \frac{\pi}{r} \right) = 1.$$

Gordon showed that the only solutions to

$$1 + \cos \phi_1 + \cos \phi_2 + \cos \phi_3 = 0$$

of the form  $\phi_i = \pi m_i/n_i$  are the permutations of  $(\frac{2}{3}\pi, \frac{2}{3}\pi, \frac{1}{3}\pi)$  and  $(\frac{2}{3}\pi, \frac{2}{5}\pi, \frac{4}{5}\pi)$ . This gives three permutations of  $(3, 3, 4)$  and six of  $(3, 5, \frac{5}{3})$  as possible solutions to the first equation. Plugging back in gives the SCHLÄFLI SYMBOLS of possible regular polyhedra as  $\{3, 3\}$ ,  $\{3, 4\}$ ,  $\{4, 3\}$ ,  $\{3, 5\}$ ,  $\{5, 3\}$ ,  $\{3, \frac{5}{2}\}$ ,  $\{\frac{5}{2}, 3\}$ ,  $\{5, \frac{5}{2}\}$ , and  $\{\frac{5}{2}, 5\}$  (Coxeter 1973, pp. 107–109). The first five of

these are the PLATONIC SOLIDS and the remaining four the KEPLER-POINSOT SOLIDS.

Every regular polyhedron has  $e + 1$  axes of symmetry, where  $e$  is the number of EDGES, and  $3h/2$  PLANES of symmetry, where  $h$  is the number of sides of the corresponding PETRIE POLYGON.

#### Regular Prime

A PRIME which does not DIVIDE the CLASS NUMBER  $h(p)$  of the CYCLOTOMIC FIELD obtained by adjoining a PRIMITIVE  $p$ TH ROOT of unity to the rational FIELD. A PRIME  $p$  is regular IFF  $p$  does not divide the NUMERATORS of the BERNOULLI NUMBERS  $B_{10}, B_{12}, \dots, B_{2p-2}$ . A PRIME which is not regular is said to be an IRREGULAR PRIME.

In 1915, Jensen proved that there are infinitely many IRREGULAR PRIMES. It has not yet been proven that there are an INFINITE number of regular primes (Guy 1994, p. 145). Of the 283,145 PRIMES  $< 4 \times 10^6$ , 171,548 (or 60.59%) are regular (the conjectured FRACTION is  $e^{-1/2} \approx 60.65\%$ ). The first few are 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 41, 43, 47, ... (Sloane's A007703).

#### Regular Ring

In the sense of von Neumann, a regular ring is a RING  $R$  such that for all  $a \in R$ , there exists a  $b \in R$  satisfying  $a = aba$ .

see also REGULAR LOCAL RING, RING

#### References

- Jacobson, N. *Basic Algebra II*, 2nd ed. New York: W. H. Freeman, p. 196, 1989.

#### Regular Sequence

Let there be two PARTICULARLY WELL-BEHAVED FUNCTIONS  $F(x)$  and  $p_\tau(x)$ . If the limit

$$\lim_{\tau \rightarrow 0} \int_{-\infty}^{\infty} p_\tau(x) F(x) dx$$

exists, then  $p_\tau(x)$  is a regular sequence of PARTICULARLY WELL-BEHAVED FUNCTIONS.

#### Regular Singular Point

Consider a second-order ORDINARY DIFFERENTIAL EQUATION

$$y'' + P(x)y' + Q(x)y = 0.$$

If  $P(x)$  and  $Q(x)$  remain FINITE at  $x = x_0$ , then  $x_0$  is called an ORDINARY POINT. If either  $P(x)$  or  $Q(x)$  diverges as  $x \rightarrow x_0$ , then  $x_0$  is called a singular point. If either  $P(x)$  or  $Q(x)$  diverges as  $x \rightarrow x_0$  but  $(x - x_0)P(x)$  and  $(x - x_0)^2 Q(x)$  remain FINITE as  $x \rightarrow x_0$ , then  $x = x_0$  is called a regular singular point (or NONESSENTIAL SINGULARITY).

see also IRREGULAR SINGULARITY, SINGULAR POINT (DIFFERENTIAL EQUATION)

#### Regular Singularity

see REGULAR SINGULAR POINT

#### Regular Surface

A SUBSET  $M \subset \mathbb{R}^n$  is called a regular surface if for each point  $p \in M$ , there exists a NEIGHBORHOOD  $V$  of  $p$  in  $\mathbb{R}^n$  and a MAP  $x : U \rightarrow \mathbb{R}^n$  of a OPEN SET  $U \subset \mathbb{R}^2$  onto  $V \cap M$  such that

1.  $x$  is differentiable,
2.  $x : U \rightarrow V \cap M$  is a HOMEOMORPHISM,
3. Each map  $x : U \rightarrow M$  is a REGULAR PATCH.

Any open subset of a regular surface is also a regular surface.

see also REGULAR PATCH

#### References

- Gray, A. "The Definition of a Regular Surface in  $\mathbb{R}^n$ ." §10.4 in *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 195–200, 1993.

### Regular Triangle Center

A TRIANGLE CENTER is regular IFF there is a TRIANGLE CENTER FUNCTION which is a POLYNOMIAL in  $\Delta$ ,  $a$ ,  $b$ , and  $c$  (where  $\Delta$  is the AREA of the TRIANGLE) such that the TRILINEAR COORDINATES of the center are

$$f(a, b, c) : f(b, c, a) : f(c, a, b).$$

The ISOGONAL CONJUGATE of a regular center is a regular center. Furthermore, given two regular centers, any two of their HARMONIC CONJUGATE POINTS are also regular centers.

see also ISOGONAL CONJUGATE, TRIANGLE CENTER, TRIANGLE CENTER FUNCTION

### Regularity Theorem

An AREA-minimizing surface (RECTIFIABLE CURRENT) bounded by a smooth curve in  $\mathbb{R}^3$  is a smooth submanifold with boundary.

see also MINIMAL SURFACE, RECTIFIABLE CURRENT

### References

Morgan, F. "What is a Surface?" *Amer. Math. Monthly* **103**, 369–376, 1996.

### Regularized Beta Function

The regularized beta function is defined by

$$I(z; a, b) = \frac{B(z; a, b)}{B(a, b)},$$

where  $B(z; a, b)$  is the incomplete BETA FUNCTION and  $B(a, b)$  is the complete BETA FUNCTION.

see also BETA FUNCTION, REGULARIZED GAMMA FUNCTION

### Regularized Gamma Function

The regularized gamma functions are defined by

$$P(a, z) = 1 - Q(a, z) \equiv \frac{\gamma(a, z)}{\Gamma(a)}$$

and

$$Q(a, z) = 1 - P(a, z) \equiv \frac{\Gamma(a, z)}{\Gamma(a)},$$

where  $\gamma(a, z)$  and  $\Gamma(a, z)$  are incomplete GAMMA FUNCTIONS and  $\Gamma(a)$  is a complete GAMMA FUNCTION. Their derivatives are

$$\begin{aligned} \frac{d}{dz} P(a, z) &= e^{-z} z^{a-1} \\ \frac{d}{dz} Q(a, z) &= -e^{-z} z^{a-1}. \end{aligned}$$

see also GAMMA FUNCTION, REGULARIZED BETA FUNCTION

### References

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 160–161, 1992.

### Regulus

The locus of lines meeting three given SKEW LINES. ("Regulus" is also the name of the brightest star in the constellation Leo.)

### Reidemeister Moves

In the 1930s, Reidemeister first rigorously proved that KNOTS exist which are distinct from the UNKNOT. He did this by showing that all KNOT deformations can be reduced to a sequence of three types of "moves," called the (I) TWIST MOVE, (II) POKE MOVE, and (III) SLIDE MOVE.

REIDEMEISTER'S THEOREM guarantees that moves I, II, and III correspond to AMBIENT ISOTOPY (moves II and III alone correspond to REGULAR ISOTOPY). He then defined the concept of COLORABILITY, which is invariant under Reidemeister moves.

see also AMBIENT ISOTOPY, COLORABLE, MARKOV MOVES, REGULAR ISOTOPY, UNKNOT

### Reidemeister's Theorem

Two LINKS can be continuously deformed into each other IFF any diagram of one can be transformed into a diagram of the other by a sequence of REIDEMEISTER MOVES.

see also REIDEMEISTER MOVES

### Reinhardt Domain

A Reinhardt domain with center  $c$  is a DOMAIN  $D$  in  $C^n$  such that whenever  $D$  contains  $z_0$ , the DOMAIN  $D$  also contains the closed POLYDISK.

Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics*. Cambridge, MA: MIT Press, p. 101, 1980.

### Relation

A relation is any SUBSET of a CARTESIAN PRODUCT. For instance, a SUBSET of  $A \times B$ , called a (binary) "relation from  $A$  to  $B$ ," is a collection of ORDERED PAIRS  $(a, b)$  with first components from  $A$  and second components from  $B$ , and, in particular, a SUBSET of  $A \times A$  is called a "relation on  $A$ ." For a binary relation  $R$ , one often writes  $aRb$  to mean that  $(a, b)$  is in  $R$ .

see also ADJACENCY RELATION, ANTISYMMETRIC RELATION, ARGUMENT ADDITION RELATION, ARGUMENT MULTIPLICATION RELATION, COVER RELATION, EQUIVALENCE RELATION, IRREFLEXIVE, PARTIAL ORDER, RECURRENCE RELATION, REFLECTION RELATION, REFLEXIVE RELATION, SYMMETRIC RELATION, TRANSITIVE, TRANSLATION RELATION

### Relative Error

Let the true value of a quantity be  $x$  and the measured or inferred value  $x_0$ . Then the relative error is defined by

$$\delta x = \frac{\Delta x}{x} = \frac{x_0 - x}{x} = \frac{x_0}{x} - 1,$$

where  $\Delta x$  is the ABSOLUTE ERROR. The relative error of the QUOTIENT or PRODUCT of a number of quantities is less than or equal to the SUM of their relative errors. The PERCENTAGE ERROR is 100% times the relative error.

see also ABSOLUTE ERROR, ERROR PROPAGATION, PERCENTAGE ERROR

#### References

### Relative Extremum

A RELATIVE MAXIMUM or RELATIVE MINIMUM, also called a LOCAL EXTREMUM.

see also EXTREMUM, GLOBAL EXTREMUM, RELATIVE MAXIMUM, RELATIVE MINIMUM

### Relative Maximum

A MAXIMUM within some NEIGHBORHOOD which need not be a GLOBAL MAXIMUM.

see also GLOBAL MAXIMUM, MAXIMUM, RELATIVE MINIMUM

### Relative Minimum

A MINIMUM within some NEIGHBORHOOD which need not be a GLOBAL MINIMUM.

see also GLOBAL MINIMUM, MINIMUM, RELATIVE MAXIMUM

### Relatively Prime

Two integers are relatively prime if they share no common factors (divisors) except 1. Using the notation  $(m, n)$  to denote the GREATEST COMMON DIVISOR, two integers  $m$  and  $n$  are relatively prime if  $(m, n) = 1$ . Relatively prime integers are sometimes also called STRANGERS or COPRIME and are denoted  $m \perp n$ .

The probability that two INTEGERS picked at random are relatively prime is  $[\zeta(2)]^{-1} = 6/\pi^2$ , where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION. This result is related to the fact that the GREATEST COMMON DIVISOR of  $m$

and  $n$ ,  $(m, n) = k$ , can be interpreted as the number of LATTICE POINTS in the PLANE which lie on the straight LINE connecting the VECTORS  $(0, 0)$  and  $(m, n)$  (excluding  $(m, n)$  itself). In fact  $6/\pi^2$  the fractional number of LATTICE POINTS VISIBLE from the ORIGIN (Castellanos 1988, pp. 155–156).

Given three INTEGERS chosen at random, the probability that no common factor will divide them all is

$$[\zeta(3)]^{-1} \approx 1.202^{-1} = 0.832\dots,$$

where  $\zeta(3)$  is APÉRY'S CONSTANT. This generalizes to  $k$  random integers (Schoenfeld 1976).

### Remainder

In general, a remainder is a quantity "left over" after performing a particular algorithm. The term is most commonly used to refer to the number left over when two integers are divided by each other in INTEGER DIVISION. For example,  $55 \setminus 7 = 7$ , with a remainder of 6. Of course in real division, there is no such thing as a remainder since, for example,  $55/7 = 7 + 6/7$ .

The term remainder is also sometimes to the RESIDUE of a CONGRUENCE.

see also DIVISION, INTEGER DIVISION, RESIDUE (CONGRUENCE)

### Remainder Theorem

see POLYNOMIAL REMAINDER THEOREM

**Rembs' Surfaces**

A special class of ENNEPER'S SURFACES which can be given parametrically by

$$x = a(U \cos u - U' \sin u) \quad (1)$$

$$y = -a(U \sin u + U' \cos u) \quad (2)$$

$$z = v - aV', \quad (3)$$

where

$$U \equiv \frac{\cosh(u\sqrt{C})}{\sqrt{C}} \quad (4)$$

$$V \equiv \frac{\cos(v\sqrt{C+1})}{\sqrt{C+1}} \quad (5)$$

$$a \equiv \frac{2V}{(C+1)(U^2 - V^2)}. \quad (6)$$

The value of  $v$  is restricted to

$$|v| \leq v_0 \equiv \frac{\pi}{2\sqrt{C+1}} \quad (7)$$

(Reckziegel 1986), and the values  $v = \pm v_0$  correspond to the ends of the cleft in the surface.

**Removable Crossing**

see REDUCIBLE CROSSING

**Removable Singularity**

A SINGULAR POINT  $z_0$  of a FUNCTION  $f(z)$  for which it is possible to assign a COMPLEX NUMBER in such a way that  $f(z)$  becomes ANALYTIC. A more precise way of defining a removable singularity is as a SINGULARITY  $z_0$  of a function  $f(z)$  about which the function  $f(z)$  is bounded. For example, the point  $x_0 = 0$  is a removable singularity in the SINC FUNCTION  $\text{sinc } x = \sin x/x$ , since this function satisfies  $\text{sinc } 0 = 1$ .

**Rencontres Number**

see DERANGEMENT, SUBFACTORIAL

**Rendezvous Values**

see MAGIC GEOMETRIC CONSTANTS

**Rényi's Parking Constants**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Given the CLOSED INTERVAL  $[0, x]$  with  $x > 1$ , let 1-D "cars" of unit length be parked randomly on the interval. The MEAN number  $M(x)$  of cars which can fit (without overlapping!) satisfies

$$M(x) = \begin{cases} 0 & \text{for } 0 \leq x < 1 \\ 1 + \frac{2}{x-1} \int_0^{x-1} M(y) dy & \text{for } x \geq 1. \end{cases} \quad (1)$$

The mean density of the cars for large  $x$  is

$$m \equiv \lim_{x \rightarrow \infty} \frac{M(x)}{x} = \int_0^\infty \exp\left(-2 \int_0^x \frac{1-e^{-y}}{y} dy\right) dx = 0.7475979203 \dots \quad (2)$$

Furthermore,

$$M(x) = mx + m - 1 + \mathcal{O}(x^{-n}) \quad (3)$$

for all  $n$  (Rényi 1958), which was strengthened by Dvoretzky and Robbins (1964) to

$$M(x) = mx + m - 1 + \mathcal{O}\left[\left(\frac{2e}{x}\right)^{x-3/2}\right]. \quad (4)$$

Dvoretzky and Robbins (1964) also proved that

$$\inf_{x \leq t \leq x+1} \frac{M(t)+1}{t+1} \leq m \leq \sup_{x \leq t \leq x+1} \frac{M(t)+1}{t+1}. \quad (5)$$

Let  $V(x)$  be the variance of the number of cars, then Dvoretzky and Robbins (1964) and Mannion (1964) showed that

$$\begin{aligned} v &\equiv \lim_{x \rightarrow \infty} \frac{V(x)}{x} \\ &= 2 \int_0^\infty \left\{ x \int_0^1 e^{-xy} R_2(y) dy + x^2 \left[ \int_0^\infty e^{-xy} R_1(y) dy \right]^2 \right\} \\ &\quad \times \exp\left(-2 \int_0^x \frac{1-e^{-y}}{y} dy\right) dx = 0.038156 \dots, \end{aligned} \quad (6)$$

where

$$R_1(x) = M(x) - mx - m + 1 \quad (7)$$

$$R_2(x) = \begin{cases} (1-m-mx)^2 & \text{for } 0 \leq x \leq 1 \\ 4(1-m)^2 & \text{for } x = 1 \\ \frac{2}{x-1} \left[ \int_0^{x-1} R_2(y) dy + \int_0^{x-1} R_1(y) R_1(x-y-1) dy \right], & \text{for } x > 1 \end{cases} \quad (8)$$

and the numerical value is due to Blaisdell and Solomon (1970). Dvoretzky and Robbins (1964) also proved that

$$\inf_{x \leq t \leq x+1} \frac{V(t)}{t+1} \leq v \leq \sup_{x \leq t \leq x+1} \frac{V(t)}{t+1}, \quad (9)$$

and that

$$V(x) = vx + v + \mathcal{O}\left[\left(\frac{4e}{x}\right)^{x-4}\right]. \quad (10)$$

Palasti (1960) conjectured that in 2-D,

$$\lim_{x,y \rightarrow \infty} \frac{M(x,y)}{xy} = m^2, \quad (11)$$

but this has not yet been proven or disproven (Finch).

#### Repartition

see ADÉLE

#### Repdigit

A number composed of a single digit is called a repdigit. If the digits are all 1s, the repdigit is called a REPUNIT. The BEAST NUMBER 666 is a repdigit.

see also KEITH NUMBER, REPUNIT

#### Repeating Decimal

A number whose decimal representation eventually becomes periodic (i.e., the same sequence of digits repeats indefinitely) is called a repeating decimal. Numbers such as 0.5 can be regarded as repeating decimals since  $0.5 = 0.5000\dots = 0.4999\dots$ . All RATIONAL NUMBERS have repeating decimals, e.g.,  $1/11 = 0.\overline{09}$ . However, TRANSCENDENTAL NUMBERS, such as  $\pi = 3.141592\dots$  do not.

see FULL REPTEND PRIME

#### Representation

The representation of a GROUP  $G$  on a COMPLEX VECTOR SPACE  $V$  is a group action of  $G$  on  $V$  by linear transformations. Two finite dimensional representations  $\pi$  on  $V$  and  $\pi'$  on  $V'$  are equivalent if there is an invertible linear map  $E : V \mapsto V'$  such that  $\pi'(g)E = E\pi(g)$  for all  $g \in G$ .  $\pi$  is said to be irreducible if it has no proper NONZERO invariant SUBSPACES.

#### Repunit

A (generalized) repunit to the base  $b$  is a number of the form

$$M_n^b = \frac{b^n - 1}{b - 1}.$$

The term "repunit" was coined by Beiler (1966), who also gave the first tabulation of known factors. Repunits  $M_n = M_n^2 = 2^n - 1$  with  $b = 2$  are called MERSENNE

NUMBERS. If  $b = 10$ , the number is called a repunit (since the digits are all 1s). A number of the form

$$R_n = \frac{10^n - 1}{10 - 1} = R_n = \frac{10^n - 1}{9}$$

is therefore a (decimal) repunit of order  $n$ .

$b$	Sloane	$b$ -Repunits
2	000225	1, 3, 7, 15, 31, 63, 127, ...
3	003462	1, 4, 13, 40, 121, 364, ...
4	002450	1, 5, 21, 85, 341, 1365, ...
5	003463	1, 6, 31, 156, 781, 3906, ...
6	003464	1, 7, 43, 259, 1555, 9331, ...
7	023000	1, 8, 57, 400, 2801, 19608, ...
8	023001	1, 9, 73, 585, 4681, 37449, ...
9	002452	1, 10, 91, 820, 7381, 66430, ...
10	002275	1, 11, 111, 1111, 11111, ...
11	016123	1, 12, 133, 1464, 16105, 177156, ...
12	016125	1, 13, 157, 1885, 22621, 271453, ...

Williams and Seah (1979) factored generalized repunits for  $3 \leq b \leq 12$  and  $2 \leq n \leq 1000$ . A (base-10) repunit can be PRIME only if  $n$  is PRIME, since otherwise  $10^{ab} - 1$  is a BINOMIAL NUMBER which can be factored algebraically. In fact, if  $n = 2a$  is EVEN, then  $10^{2a} - 1 = (10^a - 1)(10^a + 1)$ . The only base-10 repunit PRIMES  $R_n$  for  $n \leq 16,500$  are  $n = 2, 19, 23, 317$ , and 1031 (Sloane's A004023; Madachy 1979, Williams and Dubner 1986, Ball and Coxeter 1987). The number of factors for the base-10 repunits for  $n = 1, 2, \dots$  are 1, 2, 2, 2, 5, 2, 4, 4, 4, 2, 7, 3, ... (Sloane's A046053).

$b$	Sloane	$n$ of Prime $b$ -Repunits
2	000043	2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, ...
3	028491	3, 7, 13, 71, 103, 541, 1091, 1367, ...
5	004061	3, 7, 11, 13, 47, 127, 149, 181, 619, ...
6	004062	2, 3, 7, 29, 71, 127, 271, 509, 1049, ...
7	004063	5, 13, 131, 149, 1699, ...
10	004023	2, 19, 23, 317, 1031, ...
11	005808	17, 19, 73, 139, 907, 1907, 2029, 4801, ...
12	004064	2, 3, 5, 19, 97, 109, 317, 353, 701, ...

A table of the factors not obtainable algebraically for generalized repunits (a continuously updated version of Brillhart *et al.* 1988) is maintained online. These tables include factors for  $10^n - 1$  (with  $n \leq 209$  odd) and  $10^n + 1$  (for  $n \leq 210$  EVEN and ODD) in the files <ftp://sable.ox.ac.uk/pub/math/cunningham/10-> and <ftp://sable.ox.ac.uk/pub/math/cunningham/10+>. After algebraically factoring  $R_n$ , these are sufficient for complete factorizations. Yates (1982) published all the repunit factors for  $n \leq 1000$ , a portion of which are reproduced in the *Mathematica*® notebook by Weisstein.

A SMITH NUMBER can be constructed from every factored repunit.

### Residual

The residual is the sum of deviations from a best-fit curve of arbitrary form.

$$R \equiv \sum [y_i - f(x_i, a_1, \dots, a_n)]^2.$$

The residual should not be confused with the CORRELATION COEFFICIENT.

### Residual vs. Predictor Plot

A plot of  $y_i$  vs.  $e_i \equiv \hat{y}_i - y_i$ . Random scatter indicates the model is probably good. A pattern indicates a problem with the model. If the spread in  $e_i$  increases as  $y_i$  increases, the errors are called HETEROSCEDASTIC.

**Residue Class**

The residue classes of a function  $f(x)$  mod  $n$  are all possible values of the RESIDUE  $f(x)$  (mod  $n$ ). For example, the residue classes of  $x^2$  (mod 6) are  $\{0, 1, 3, 4\}$ , since

$$0^2 \equiv 0 \pmod{6}$$

$$1^2 \equiv 1 \pmod{6}$$

$$3^2 \equiv 3 \pmod{6}$$

$$4^2 \equiv 4 \pmod{6}$$

are all the possible residues. A COMPLETE RESIDUE SYSTEM is a set of integers containing one element from each class, so in this case,  $\{0, 1, 9, 4\}$  would be a COMPLETE RESIDUE SYSTEM.

The  $\phi(m)$  residue classes prime to  $m$  form a GROUP under the binary multiplication operation (mod  $m$ ), where  $\phi(m)$  is the TOTIENT FUNCTION (Shanks 1993) and the GROUP is classed a MODULO MULTIPLICATION GROUP.

**Residue (Complex Analysis)**

The constant  $a_{-1}$  in the LAURENT SERIES

$$f(z) = \sum_{n=-\infty}^{\infty} a_n (z - z_0)^n$$

of  $f(z)$  is called the residue of  $f(z)$ . The residue is a very important property of a complex function and appears in the amazing RESIDUE THEOREM of CONTOUR INTEGRATION.

see also CONTOUR INTEGRATION, LAURENT SERIES, RESIDUE THEOREM

**References**

Arfken, G. "Calculus of Residues." §7.2 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 400–421, 1985.

**Residue (Congruence)**

The number  $b$  in the CONGRUENCE  $a \equiv b \pmod{m}$  is called the residue of  $a \pmod{m}$ . The residue of large numbers can be computed quickly using CONGRUENCES. For example, to find  $37^{13} \pmod{17}$ , note that

$$37 \equiv 3$$

$$37^2 \equiv 3^2 \equiv 9 \equiv -8$$

$$37^4 \equiv 81 \equiv -4$$

$$37^8 \equiv 16 \equiv -1,$$

so

$$37^{13} \equiv 37^{1+4+8} \equiv 3(-4)(-1) \equiv 12 \pmod{17}.$$

**Residue Index**

$p-1$  divided by the HAUPT-EXPONENT of a base  $b$  mod  $p$  for a given PRIME  $p$ .

see also HAUPT-EXPONENT

**Residue Theorem (Complex Analysis)**

Given a complex function  $f(z)$ , consider the LAURENT SERIES

$$f(z) = \sum_{n=-\infty}^{\infty} a_n (z - z_0)^n. \quad (1)$$

Integrate term by term using a closed contour  $\gamma$  encircling  $z_0$ ,

$$\begin{aligned} \int_{\gamma} f(z) dz &= \sum_{n=-\infty}^{\infty} a_n \int_{\gamma} (z - z_0)^n dz \\ &= \sum_{n=-\infty}^{-2} a_n \int_{\gamma} (z - z_0)^n dz \\ &\quad + a_{-1} \int_{\gamma} \frac{dz}{z - z_0} + \sum_{n=0}^{\infty} a_n \int_{\gamma} (z - z_0)^n dz. \end{aligned} \quad (2)$$

The CAUCHY INTEGRAL THEOREM requires that the first and last terms vanish, so we have

$$\int_{\gamma} f(z) dz = a_{-1} \int_{\gamma} \frac{dz}{z - z_0}. \quad (3)$$

But we can evaluate this function (which has a POLE at  $z_0$ ) using the CAUCHY INTEGRAL FORMULA,

$$f(z_0) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(z) dz}{z - z_0}. \quad (4)$$

This equation must also hold for the constant function  $f(z) = 1$ , in which case it is also true that  $f(z_0) = 1$ , so

$$1 = \frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z - z_0}, \quad (5)$$

$$\int_{\gamma} \frac{dz}{z - z_0} = 2\pi i, \quad (6)$$

and (3) becomes

$$\int_{\gamma} f(z) dz = 2\pi i a_{-1}. \quad (7)$$

The quantity  $a_{-1}$  is known as the RESIDUE of  $f(z)$  at  $z_0$ . Generalizing to a curve passing through multiple poles, (7) becomes

$$\int_{\gamma} f(z) dz = 2\pi i \sum_{i=1}^{\text{poles in } \gamma} n(\gamma, z_0^{(i)}) a_{-1}^{(i)}, \quad (8)$$

where  $n$  is the WINDING NUMBER and the  $(i)$  superscript denotes the quantity corresponding to POLE  $i$ .

If the path does not completely encircle the RESIDUE, take the CAUCHY PRINCIPAL VALUE to obtain

$$\int f(z) dz = (\theta_2 - \theta_1) i a_{-1}. \quad (9)$$

If  $f$  has only ISOLATED SINGULARITIES, then

$$\sum_{z_0^{(i)} \in \mathbb{C}^*} a_{-1}^{(i)} = 0. \quad (10)$$

The residues may be found without explicitly expanding into a LAURENT SERIES as follows.

$$f(z) = \sum_{n=-\infty}^{\infty} a_n (z - z_0)^n. \quad (11)$$

If  $f(z)$  has a POLE of order  $m$  at  $z_0$ , then  $a_n = 0$  for  $n < -m$  and  $a_{-m} \neq 0$ . Therefore,

$$f(z) = \sum_{n=-m}^{\infty} a_n (z - z_0)^n = \sum_{n=0}^{\infty} a_{-m+n} (z - z_0)^{-m+n} \quad (12)$$

$$(z - z_0)^m f(z) = \sum_{n=0}^{\infty} a_{-m+n} (z - z_0)^n \quad (13)$$

$$\begin{aligned} \frac{d}{dz} [(z - z_0)^m f(z)] &= \sum_{n=0}^{\infty} n a_{-m+n} (z - z_0)^{n-1} \\ &= \sum_{n=1}^{\infty} n a_{-m+n} (z - z_0)^{n-1} \\ &= \sum_{n=0}^{\infty} (n+1) a_{-m+n+1} (z - z_0)^n \end{aligned} \quad (14)$$

$$\begin{aligned} \frac{d^2}{dz^2} [(z - z_0)^m f(z)] &= \sum_{n=0}^{\infty} n(n+1) a_{-m+n+1} (z - z_0)^{n-1} \\ &= \sum_{n=1}^{\infty} n(n+1) a_{-m+n+1} (z - z_0)^{n-1} \\ &= \sum_{n=0}^{\infty} (n+1)(n+2) a_{-m+n+2} (z - z_0)^n. \end{aligned} \quad (15)$$

Iterating,

$$\begin{aligned} \frac{d^{m-1}}{dz^{m-1}} [(z - z_0)^m f(z)] &= \sum_{n=0}^{\infty} (n+1)(n+2)(n+m-1) a_{n-1} (z - z_0)^n \\ &= (m-1)! a_{-1} \\ &+ \sum_{n=1}^{\infty} (n+1)(n+2)(n+m-1) a_{n-1} (z - z_0)^{n-1}. \end{aligned} \quad (16)$$

So

$$\begin{aligned} \lim_{z \rightarrow z_0} \frac{d^{m-1}}{dz^{m-1}} [(z - z_0)^m f(z)] &= \lim_{z \rightarrow z_0} (m-1)! a_{-1} + 0 = (m-1)! a_{-1}, \end{aligned} \quad (17)$$

and the RESIDUE is

$$a_{-1} = \frac{1}{(m-1)!} \frac{d^{m-1}}{dz^{m-1}} [(z - z_0)^m f(z)]_{z=z_0}. \quad (18)$$

This amazing theorem says that the value of a CONTOUR INTEGRAL in the COMPLEX PLANE depends *only* on the properties of a few special points *inside* the contour.

see also CAUCHY INTEGRAL FORMULA, CAUCHY INTEGRAL THEOREM, CONTOUR INTEGRAL, LAURENT SERIES, POLE, RESIDUE (COMPLEX ANALYSIS)

### Residue Theorem (Group)

If two groups are residual to a third, every group residual to one is residual to the other. The Gambier extension of this theorem states that if two groups are pseudoresidual to a third, then every group pseudoresidual to the first with an excess greater than or equal to the excess of the first minus the excess of the second is pseudoresidual to the second, with an excess  $\geq 0$ .

### Resolution

Resolution is a widely used word with many different meanings. It can refer to resolution of equations, resolution of singularities (in ALGEBRAIC GEOMETRY), resolution of modules or more sophisticated structures, etc. In a BLOCK DESIGN, a PARTITION  $R$  of a BIBD's set of blocks  $B$  into PARALLEL CLASSES, each of which in turn partitions the set  $V$ , is called a resolution (Abel and Furino 1996).

A resolution of the MODULE  $M$  over the RING  $R$  is a complex of  $R$ -modules  $C_i$  and morphisms  $d_i$  and a MORPHISM  $\epsilon$  such that

$$\cdots \rightarrow C_i \xrightarrow{d_i} C_{i-1} \rightarrow \cdots \rightarrow C_0 \xrightarrow{\epsilon} M \rightarrow 0$$

satisfying the following conditions:

1. The composition of any two consecutive morphisms is the zero map,
2. For all  $i$ ,  $(\ker d_i)/(\operatorname{im} d_{i+1}) = 0$ ,
3.  $C_0/(\ker \epsilon) \simeq M$ ,

where  $\ker$  is the kernel and  $\operatorname{im}$  is the image. Here, the quotient

$$\frac{(\ker d_i)}{(\operatorname{im} d_{i+1})}$$

is the  $i$ th HOMOLOGY GROUP.

If all modules  $C_i$  are projective (free), then the resolution is called projective (free). There is a similar concept for resolutions "to the right" of  $M$ , which are called injective resolutions.

see also HOMOLOGY GROUP, MODULE, MORPHISM, RING

### Resolving Tree

A tree of LINKS obtained by repeatedly choosing a crossing, applying the SKEIN RELATIONSHIP to obtain two simpler LINKS, and repeating the process. The DEPTH of a resolving tree is the number of levels of links, not including the top. The DEPTH of the LINK is the minimal depth for any resolving tree of that LINK.

### Resonance Overlap

Isolated resonances in a DYNAMICAL SYSTEM can cause considerable distortion of preserved TORI in their NEIGHBORHOOD, but they do not introduce any CHAOS into a system. However, when two or more resonances are simultaneously present, they will render a system nonintegrable. Furthermore, if they are sufficiently "close" to each other, they will result in the appearance of widespread (large-scale) CHAOS.

To investigate this problem, Walker and Ford (1969) took the integrable Hamiltonian

$$H_0(I_1, I_2) = I_1 + I_2 - I_1^2 - 3I_1I_2 + I_2^2$$

and investigated the effect of adding a 2:2 resonance and a 3:2 resonance

$$H(\mathbf{I}, \theta) = H_0(\mathbf{I}) + \alpha I_1 I_2 \cos(2\theta_1 - 2\theta_2) + \beta I_1^{3/2} I_2 \cos(2\theta_1 - 3\theta_2).$$

At low energies, the resonant zones are well-separated. As the energy increases, the zones overlap and a "macroscopic zone of instability" appears. When the overlap starts, many higher-order resonances are also involved so fairly large areas of PHASE SPACE have their TORI destroyed and the ensuing CHAOS is "widespread" since trajectories are now free to wander between regions that previously were separated by nonresonant TORI.

Walker and Ford (1969) were able to numerically predict the energy at which the overlap of the resonances first occurred. They plotted the  $\theta_2$ -axis intercepts of the inner 2:2 and the outer 2:3 separatrices as a function of total energy. The energy at which they crossed was found to be identical to that at which 2:2 and 2:3 resonance zones began to overlap.

**Restricted Divisor Function**

The sum of the ALIQUOT DIVISORS of  $n$ , given by

$$s(n) \equiv \sigma(n) - n,$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. The first few values are 0, 1, 1, 3, 1, 6, 1, 7, 4, 8, 1, 16, ... (Sloane's A001065).

see also DIVISOR FUNCTION

**References**

Sloane, N. J. A. Sequence A001065/M2226 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Restricted Growth Function**

see RESTRICTED GROWTH STRING

**Restricted Growth String**

For a SET PARTITION of  $n$  elements, the  $n$ -character string  $a_1 a_2 \dots a_n$  in which each character gives the BLOCK ( $B_0, B_1, \dots$ ) into which the corresponding element belongs is called the restricted growth string (or sometimes the RESTRICTED GROWTH FUNCTION). For example, for the SET PARTITION  $\{\{1\}, \{2\}, \{3, 4\}\}$ , the restricted growth string would be 0122. If the BLOCKS are "sorted" so that  $a_1 = 0$ , then the restricted growth string satisfies the INEQUALITY

$$a_{i+1} \leq 1 + \max\{a_1, a_2, \dots, a_i\}$$

for  $i = 1, 2, \dots, n - 1$ .

**References**

Ruskey, F. "Info About Set Partitions." <http://sue.csc.uvic.ca/~cos/inf/setp/SetPartitions.html>.

**Resultant**

Given a POLYNOMIAL  $p(x)$  of degree  $n$  with roots  $\alpha_i$ ,  $i = 1, \dots, n$  and a POLYNOMIAL  $q(x)$  of degree  $m$  with roots  $\beta_j$ ,  $j = 1, \dots, m$ , the resultant is defined by

$$R(p, q) = \prod_{i=1}^n \prod_{j=1}^m (\beta_j - \alpha_i).$$

There exists an ALGORITHM similar to the EUCLIDEAN ALGORITHM for computing resultants (Pohst and Zassenhaus 1989). The resultant is the DETERMINANT

of the corresponding SYLVESTER MATRIX. Given  $p$  and  $q$ , then

$$h(x) = R(q(t), p(x - t))$$

is a POLYNOMIAL of degree  $mn$ , having as its roots all sums of the form  $\alpha_i + \beta_j$ .

**Reuleaux Polygon**

A curvilinear polygon built up of circular ARCS. The Reuleaux polygon is a generalization of the REULEAUX TRIANGLE.

see also CURVE OF CONSTANT WIDTH, REULEAUX TRIANGLE

**References**

Wagon, S. *Mathematica in Action*. New York: W. H. Freeman, pp. 52-54, 1991.

**Reuleaux Triangle**

A CURVE OF CONSTANT WIDTH constructed by drawing arcs from each VERTEX of an EQUILATERAL TRIANGLE between the other two VERTICES. It is the basis for the Harry Watt square drill bit. It has the smallest AREA for a given width of any CURVE OF CONSTANT WIDTH.

The AREA of each meniscus-shaped portion is

$$A = \frac{1}{6}\pi r^2 - \frac{1}{2}r \left( \frac{\sqrt{3}}{2}r \right) = \left( \frac{\pi}{6} - \frac{\sqrt{3}}{4} \right) r^2, \quad (1)$$

where we have subtracted the AREA of the wedge from that of the EQUILATERAL TRIANGLE. The total AREA is then

$$A = 3 \left( \frac{\pi}{6} - \frac{\sqrt{3}}{4} \right) r^2 + \frac{\sqrt{3}}{4} r^2 = \frac{\pi - \sqrt{3}}{2} r^2. \quad (2)$$

When rotated in a square, the fractional AREA covered is

$$A_{\text{covered}} = 2\sqrt{3} + \frac{1}{6}\pi = 0.9877700392\dots \quad (3)$$

The center does *not* stay fixed as the TRIANGLE is rotated, but moves along a curve composed of four arcs of an ELLIPSE (Wagon 1991).

#### Reversal

The reversal of a decimal number  $abc\dots$  is  $\dots cba$ . Ball and Coxeter (1987) consider numbers whose reversals are integral multiples of themselves. PALINDROMIC NUMBER and numbers ending with a ZERO are trivial examples. The first few nontrivial examples are 8712, 9801, 87912, 98901, 879912, 989901, 8799912, 9899901, 87128712, 87999912, 98019801, 98999901, ... (Sloane's A031877). The pattern continues for large numbers, with numbers of the form  $\underbrace{879\dots 912}$  equal to 4 times their reversals and numbers of the form  $\underbrace{989\dots 901}$  equal to 9 times their reversals. In addition, runs of numbers of either of these forms can be concatenated to yield numbers of the form  $\underbrace{879\dots 912\dots 879\dots 912}$ , equal to 4 times their reversals, and  $\underbrace{989\dots 901\dots 989\dots 901}$ , equal to 9 times their reversals.

The product of a 2-digit number and its reversal is never a SQUARE NUMBER except when the digits are the same (Ogilvy 1988). Numbers whose product is the reversal of the products of their reversals include

$$312 \times 221 = 68952$$

$$213 \times 122 = 25986$$

(Ball and Coxeter 1987, p. 14).

## Rhombic Dodecahedron

The DUAL POLYHEDRON of the CUBOCTAHEDRON, also sometimes called the RHOMBOIDAL DODECAHEDRON (Cotton 1990). Its 14 vertices are joined by 12 RHOMBUSES, and one possible way to construct it is known as the BAUSPIEL. The rhombic dodecahedron is a ZONOHEDRON and a SPACE-FILLING POLYHEDRON. The vertices are given by  $(\pm 1, \pm 1, \pm 1)$ ,  $(\pm 2, 0, 0)$ ,  $(0, \pm 2, 0)$ ,  $(0, 0, \pm 2)$ .

The edges of the CUBE-OCTAHEDRON COMPOUND intersecting in the points plotted above are the diagonals of RHOMBUSES, and the 12 RHOMBUSES form a rhombic dodecahedron (Ball and Coxeter 1987).

## Rhombic Polyhedron

A POLYHEDRON with extra square faces, given by the SCHLÄFLI SYMBOL  $r\left\{\begin{smallmatrix} p \\ q \end{smallmatrix}\right\}$ .

see also RHOMBIC DODECAHEDRON, RHOMBIC ICOSAHEDRON, RHOMBIC TRIACONTAHEDRON, SNUB POLYHEDRON, TRUNCATED POLYHEDRON

## Rhombic Triacanthedron

A ZONOHEDRON which is the DUAL POLYHEDRON of the ICOSIDODECAHEDRON. It is composed of 30 RHOMBUSES joined at 32 vertices. Ede (1958) enumerates 13 basic series of stellations of the rhombic triacanthedron, the total number of which is extremely large. Messer (1995) describes 226 stellations. The intersecting edges of the DODECAHEDRON-ICOSAHEDRON COMPOUND form the diagonals of 30 RHOMBUSES which comprise the TRIACONTAHEDRON. The CUBE 5-COMPOUND has the 30 facial planes of the rhombic triacanthedron (Ball and Coxeter 1987).

## Rhombicosacron

The DUAL POLYHEDRON of the RHOMBICOSAHEDRON.

**Rhombicosahedron**

The UNIFORM POLYHEDRON  $U_{56}$  whose DUAL POLYHEDRON is the RHOMBICOSACRON. It has WYTHOFF SYMBOL  $23\frac{5}{2}\frac{4}{3}$ . Its faces are  $20\{6\} + 30\{4\}$ . The CIRCUMRADIUS for unit edge length is

$$R = \frac{1}{2}\sqrt{7}.$$

Ball, W. W. R. and Coxeter, H. S. M. *Mathematical Recreations and Essays*, 13th ed. New York: Dover, pp. 142 and 161, 1987.

**Rhomboid**

A PARALLELOGRAM in which angles are oblique and adjacent sides are of unequal length.

see also DIAMOND, LOZENGE, PARALLELOGRAM, QUADRILATERAL, RHOMBUS, SKEW QUADRILATERAL, TRAPEZIUM, TRAPEZOID

**Rhomboidal Dodecahedron**

see RHOMBIC DODECAHEDRON

**Rhombus**

A QUADRILATERAL with both pairs of opposite sides PARALLEL and all sides the same length, i.e., an equilateral PARALLELOGRAM. The word RHOMB is sometimes

used instead of rhombus. The DIAGONALS  $p$  and  $q$  of a rhombus satisfy

$$p^2 + q^2 = 4a^2,$$

and the AREA is

$$A = \frac{1}{2}pq.$$

A rhombus whose ACUTE ANGLES are  $45^\circ$  is called a LOZENGE.

see also DIAMOND, LOZENGE, PARALLELOGRAM, QUADRILATERAL, RHOMBIC DODECAHEDRON, RHOMBIC ICOSAHEDRON, RHOMBIC TRIACONTAHEDRON, RHOMBOID, SKEW QUADRILATERAL, TRAPEZIUM, TRAPEZOID

Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, p. 225, 1976.

### Ribet's Theorem

If the TANIYAMA-SHIMURA CONJECTURE holds for all semistable ELLIPTIC CURVES, then FERMAT'S LAST THEOREM is true. Before its proof by Ribet in 1986, the theorem had been called the epsilon conjecture. It had its roots in a surprising result of G. Frey.

see also ELLIPTIC CURVE, FERMAT'S LAST THEOREM, MODULAR FORM, MODULAR FUNCTION, TANIYAMA-SHIMURA CONJECTURE

### Riccati-Bessel Functions

$$S_n(z) \equiv z j_n(z) = \sqrt{\frac{\pi z}{2}} J_{n+1/2}(z)$$

$$C_n(z) \equiv -z n_n(z) = -\sqrt{\frac{\pi z}{2}} N_{n+1/2}(z),$$

where  $j_n(z)$  and  $n_n(z)$  are SPHERICAL BESSEL FUNCTIONS OF THE FIRST and SECOND KIND.

#### References

Abramowitz, M. and Stegun, C. A. (Eds.). "Riccati-Bessel Functions." §10.3 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, p. 445, 1972.

### Riccati Differential Equation

$$y' = P(z) + Q(z)y + R(z)y^2, \quad (1)$$

where  $y' \equiv dy/dz$ . The transformation

$$w \equiv -\frac{y'}{yR(z)} \quad (2)$$

leads to the second-order linear homogeneous equation

$$R(z)y'' - [R'(z) + Q(z)R(z)]y' + [R(z)]^2 P(z)y = 0. \quad (3)$$

Another equation sometimes called the Riccati differential equation is

$$z^2 w'' + [z^2 - n(n+1)]w = 0, \quad (4)$$

which has solutions

$$w = Az j_n(z) + Bz y_n(z). \quad (5)$$

Yet another form of "the" Riccati differential equation is

$$\frac{dy}{dz} = az^n + by^2, \quad (6)$$

which is solvable by algebraic, exponential, and logarithmic functions only when  $n = -4m/(2m \pm 1)$ , for  $m = 0, 1, 2, \dots$

**Riemann's Formula**

$$J(x) = \text{Li}(x) - \sum \text{Li}(x^\rho) + \ln 2 \int_x^\infty \frac{dt}{t(t^2 - 1) \ln t},$$

where  $\text{Li}(x)$  is the LOGARITHMIC INTEGRAL, the sum is taken over all nontrivial zeros  $\rho$  (i.e., those other than  $-2, -4, \dots$ ) of the RIEMANN ZETA FUNCTION  $\zeta(s)$ , and  $J(x)$  is RIEMANN WEIGHTED PRIME-POWER COUNTING FUNCTION.

see also LOGARITHMIC INTEGRAL, PRIME NUMBER THEOREM, RIEMANN WEIGHTED PRIME-POWER COUNTING FUNCTION, RIEMANN ZETA FUNCTION

**Riemann Function**

The function obtained by approximating the RIEMANN WEIGHTED PRIME-POWER COUNTING FUNCTION  $J_2$  in

$$\pi(x) = \sum_{n=1}^{\infty} \frac{\mu(n)}{n} J_2(x^{1/n}) \quad (1)$$

by the LOGARITHMIC INTEGRAL  $\text{Li}(x)$ . This gives

$$R(n) \equiv 1 + \sum_{k=1}^{\infty} \frac{1}{k\zeta(k+1)} \frac{(\ln n)^k}{k!} \quad (2)$$

$$= \sum_{m=1}^{\infty} \frac{\mu(m)}{m} \text{Li}(n^{1/m}), \quad (3)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION,  $\mu(n)$  is the MÖBIUS FUNCTION, and  $\text{Li}(x)$  is the LOGARITHMIC INTEGRAL. Then

$$\pi(x) = R(x) - \sum_p R(x^p), \quad (4)$$

where  $\pi$  is the PRIME COUNTING FUNCTION. Ramanujan independently derived the formula for  $R(n)$ , but nonrigorously (Berndt 1994, p. 123).

#### Riemann Hypothesis

First published in Riemann (1859), the Riemann hypothesis states that the nontrivial ROOTS of the RIEMANN ZETA FUNCTION

$$\zeta(s) \equiv \sum_{n=1}^{\infty} \frac{1}{n^s}, \quad (1)$$

where  $s \in \mathbb{C}$  (the COMPLEX NUMBERS), all lie on the "CRITICAL LINE"  $\Re[s] = 1/2$ , where  $\Re[z]$  denotes the REAL PART of  $z$ . The Riemann hypothesis is also known as ARTIN'S CONJECTURE.

In 1914, Hardy proved that an INFINITE number of values for  $s$  can be found for which  $\zeta(s) = 0$  and  $\Re[s] = 1/2$ . However, it is not known if *all* nontrivial roots  $s$  satisfy  $\Re[s] = 1/2$ , so the conjecture remains open. André Weil proved the Riemann hypothesis to be true for field functions (Weil 1948, Eichler 1966, Ball and Coxeter 1987). In 1974, Levin showed that at least 1/3 of the ROOTS must lie on the CRITICAL LINE (Le Lionnais 1983), a result which has since been sharpened to 40% (Vardi 1991, p. 142). It is known that the zeros are symmetrically placed about the line  $\Im[s] = 0$ .

The Riemann hypothesis is equivalent to  $\Lambda \leq 0$ , where  $\Lambda$  is the DE BRUIJN-NEWMAN CONSTANT (Csordas *et*

*al.* 1994). It is also equivalent to the assertion that for some constant  $c$ ,

$$|\text{Li}(x) - \pi(x)| \leq c\sqrt{x} \ln x, \quad (2)$$

where  $\text{Li}(x)$  is the LOGARITHMIC INTEGRAL and  $\pi$  is the PRIME COUNTING FUNCTION (Wagon 1991).

The hypothesis was computationally tested and found to be true for the first  $2 \times 10^8$  zeros by Brent *et al.* (1979), a limit subsequently extended to the first  $1.5 \times 10^9 + 1$  zeros by Brent *et al.* (1979). Brent's calculation covered zeros  $\sigma + it$  in the region  $0 < t < 81,702,130.19$ .

There is also a finite analog of the Riemann hypothesis concerning the location of zeros for function fields defined by equations such as

$$ay^l + bz^m + c = 0. \quad (3)$$

This hypothesis, developed by Weil, is analogous to the usual Riemann hypothesis. The number of solutions for the particular cases  $(l, m) = (2, 2), (3, 3), (4, 4)$ , and  $(2, 4)$  were known to Gauss.

### Riemann Integral

The Riemann integral is the INTEGRAL normally encountered in CALCULUS texts and used by physicists and engineers. Other types of integrals exist (e.g., the LEBESGUE INTEGRAL), but are unlikely to be encountered outside the confines of advanced mathematics texts.

The Riemann integral is based on the JORDAN MEASURE, and defined by taking a limit of a RIEMANN SUM,

$$\int_b^a f(x) dx \equiv \lim_{\max \Delta x_k \rightarrow 0} \sum_{k=1}^n f(x_k^*) \Delta x_k \quad (1)$$

$$\iint f(x, y) dA \equiv \lim_{\max \Delta A_k \rightarrow 0} \sum_{k=1}^n f(x_k^*, y_k^*) \Delta A_k \quad (2)$$

$$\iiint f(x, y, z) dV \equiv \lim_{\max \Delta V_k \rightarrow 0} \sum_{k=1}^n f(x_k^*, y_k^*, z_k^*) \Delta V_k, \quad (3)$$

where  $a \leq x \leq b$  and  $x_k^*$ ,  $y_k^*$ , and  $z_k^*$  are arbitrary points in the intervals  $\Delta x_k$ ,  $\Delta y_k$ , and  $\Delta z_k$ , respectively. The value  $\max \Delta x_k$  is called the MESH SIZE of a partition of the interval  $[a, b]$  into subintervals  $\Delta x_k$ .

As an example of the application of the Riemann integral definition, find the AREA under the curve  $y = x^r$  from 0 to  $a$ . Divide  $(a, b)$  into  $n$  segments, so  $\Delta x_k = \frac{b-a}{n} \equiv h$ , then

$$f(x_1) = f(0) = 0 \quad (4)$$

$$f(x_2) = f(\Delta x_k) = h^r \quad (5)$$

$$f(x_3) = f(2\Delta x_k) = (2h)^r. \quad (6)$$

By induction

$$f(x_k) = f([k-1]\Delta x_k) = [(k-1)h]^r = h^r(k-1)^r, \quad (7)$$

so

$$f(x_k) \Delta x_k = h^{r+1}(k-1)^r \quad (8)$$

$$\sum_{k=1}^n f(x_k) \Delta x_k = h^{r+1} \sum_{k=1}^n (k-1)^r. \quad (9)$$

For example, take  $r = 2$ .

$$\begin{aligned} \sum_{k=1}^n f(x_k) \Delta x_k &= h^3 \sum_{k=1}^n (k-1)^2 \\ &= h^3 \left( \sum_{k=1}^n k^2 - 2 \sum_{k=1}^n k + \sum_{k=1}^n 1 \right) \\ &= h^3 \left[ \frac{n(n+1)(2n+1)}{6} - 2 \frac{n(n+1)}{2} + n \right], \end{aligned} \quad (10)$$

so

$$\begin{aligned} I &\equiv \lim_{n \rightarrow \infty} \sum_{k=1}^n f(x_k^*) \Delta x_k = \lim_{n \rightarrow \infty} \sum_{k=1}^n f(x_k) \Delta x_k \\ &= \lim_{n \rightarrow \infty} h^3 \left[ \frac{n(n+1)(2n+1)}{6} - 2 \frac{n(n+1)}{2} + n \right] \\ &= a^3 \lim_{n \rightarrow \infty} \left[ \frac{n(n+1)(2n+1)}{6n^3} - \frac{n(n+1)}{n^3} + \frac{n}{n^3} \right] \\ &= \frac{1}{3} a^3. \end{aligned} \quad (11)$$

### References

Kestelman, H. "Riemann Integration." Ch. 2 in *Modern Theories of Integration*, 2nd rev. ed. New York: Dover, pp. 33-66, 1960.

### Riemann's Integral Theorem

Associated with an irreducible curve of GENUS (CURVE)  $p$ , there are  $p$  LINEARLY INDEPENDENT integrals of the first sort. The ROOTS of the integrands are groups of the canonical series, and every such group will give rise to exactly one integral of the first sort.

### References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 274, 1959.

### Riemann-Lebesgue Lemma

Sometimes also called MERCER'S THEOREM.

$$\lim_{n \rightarrow \infty} \int_a^b K(\lambda, z) C \sin(nz) dz = 0$$

for arbitrarily large  $C$  and "nice"  $K(\lambda, z)$ . Gradshteyn and Ryzhik (1979) state the lemma as follows. If  $f(x)$  is integrable on  $[\pi, \pi]$ , then

$$\lim_{t \rightarrow \infty} \int_{-\pi}^{\pi} f(x) \sin(tx) dx \rightarrow 0$$

and

$$\lim_{t \rightarrow \infty} \int_{-\pi}^{\pi} f(x) \cos(tx) dx \rightarrow 0.$$

### Riemann-Mangoldt Function

$$\begin{aligned} f(x) &= \sum_{n>1}^{\infty} \frac{\pi_0(x^{1/n})}{n} \\ &= \text{Li}(x) - \sum_{\substack{\text{nontrivial } \rho \\ \zeta(\rho)=0}} \text{ei}(\rho \ln x) - \ln 2 \\ &\quad + \int_x^{\infty} \frac{dt}{t(t^2-1) \ln t}, \end{aligned} \quad (1)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION,  $\text{Li}(x)$  is the LOGARITHMIC INTEGRAL and  $\text{ei}(x)$  is the EXPONENTIAL INTEGRAL. The MANGOLDT FUNCTION is given by

$$\Lambda(n) = \begin{cases} \ln p & \text{if } n = p^m \text{ for } (m \geq 1) \text{ and } p \text{ prime} \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

$$-\frac{\zeta'(x)}{\zeta(x)} = \sum_{n=1}^{\infty} \frac{\Lambda(n)}{n^x} \quad (3)$$

for  $\Re[s] > 1$ .

$$J(x) = \sum_{n \leq x} \frac{\Lambda(n)}{\ln n}. \quad (4)$$

The SUMMATORY Riemann-Mangoldt function is defined by

$$\psi(x) = \sum_{n \leq x} \Lambda(n) = \theta(x) + \theta(x^{1/2}) + \dots \quad (5)$$

### Riemann Mapping Theorem

Let  $z_0$  be a point in a simply connected region  $R \neq \mathbb{C}$ . Then there is a unique ANALYTIC FUNCTION  $w = f(z)$  mapping  $R$  one-to-one onto the DISK  $|w| < 1$  such that  $f(z_0) = 0$  and  $f'(z_0) = 0$ . The COROLLARY guarantees that any two simply connected regions except  $\mathbb{R}^2$  can be mapped CONFORMALLY onto each other.

### Riemann's Moduli Problem

Find an ANALYTIC parameterization of the compact RIEMANN SURFACES in a fixed HOMOMORPHISM class. The AHLFORS-BERS THEOREM proved that RIEMANN'S MODULI SPACE gives the solution.

see also AHLFORS-BERS THEOREM, RIEMANN'S MODULI SPACE

### Riemann's Moduli Space

Riemann's moduli space  $R_p$  is the space of ANALYTIC EQUIVALENCE CLASSES of RIEMANN SURFACES of fixed GENUS  $p$ .

see also AHLFORS-BERS THEOREM, RIEMANN'S MODULI PROBLEM, RIEMANN SURFACE

### Riemann $P$ -Differential Equation

$$\begin{aligned} \frac{d^2 u}{dz^2} + \left[ \frac{1 - \alpha - \alpha'}{z - a} + \frac{1 - \beta - \beta'}{z - b} + \frac{1 - \gamma - \gamma'}{z - c} \right] \frac{du}{dz} \\ + \left[ \frac{\alpha\alpha'(a - b)(a - c)}{z - a} + \frac{\beta\beta'(b - c)(b - a)}{z - b} \right. \\ \left. + \frac{\gamma\gamma'(c - a)(c - b)}{z - c} \right] \frac{u}{(z - a)(z - b)(z - c)} = 0, \end{aligned}$$

where

$$\alpha + \alpha' + \beta + \beta' + \gamma + \gamma' = 1.$$

Solutions are RIEMANN  $P$ -SERIES (Abramowitz and Stegun 1972, pp. 564–565).

### Riemann $P$ -Series

The solutions to the RIEMANN  $P$ -DIFFERENTIAL EQUATION

$$z = P \left\{ \begin{matrix} a & b & c \\ \alpha & \beta & \gamma \\ \alpha' & \beta' & \gamma' \end{matrix} ; z \right\}.$$

Solutions are given in terms of the HYPERGEOMETRIC FUNCTION by

$$\begin{aligned} u_1 &= \left( \frac{z - a}{z - b} \right)^{\alpha} \left( \frac{z - c}{z - b} \right)^{\gamma} \\ &\quad \times {}_2F_1(\alpha + \beta + \gamma, \alpha + \beta' + \gamma; 1 + \alpha - \alpha'; \lambda) \\ u_2 &= \left( \frac{z - a}{z - b} \right)^{\alpha'} \left( \frac{z - c}{z - b} \right)^{\gamma} \\ &\quad \times {}_2F_1(\alpha' + \beta + \gamma, \alpha' + \beta' + \gamma; 1 + \alpha' - \alpha; \lambda) \\ u_3 &= \left( \frac{z - a}{z - b} \right)^{\alpha} \left( \frac{z - c}{z - b} \right)^{\gamma'} \\ &\quad \times {}_2F_1(\alpha + \beta + \gamma', \alpha + \beta' + \gamma'; 1 + \alpha - \alpha'; \lambda) \\ u_4 &= \left( \frac{z - a}{z - b} \right)^{\alpha'} \left( \frac{z - c}{z - b} \right)^{\gamma'} \\ &\quad \times {}_2F_1(\alpha' + \beta + \gamma', \alpha' + \beta' + \gamma'; 1 + \alpha' - \alpha; \lambda), \end{aligned}$$

where

$$\lambda \equiv \frac{(z - a)(c - b)}{(z - b)(c - a)}.$$

## Riemann-Siegel Functions

For a REAL POSITIVE  $t$ , the Riemann-Siegel  $Z$  function is defined by

$$Z(t) \equiv e^{i\vartheta(t)} \zeta\left(\frac{1}{2} + it\right).$$

The top plot superposes  $Z(t)$  (thick line) on  $|\zeta(\frac{1}{2} + it)|$ , where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION.

The Riemann-Siegel theta function appearing above is defined by

$$\begin{aligned} \vartheta &\equiv \Im[\ln \Gamma(\tfrac{1}{4} + \tfrac{1}{2}it) - \tfrac{1}{2}t \ln \pi] \\ &= \arg[\Gamma(\tfrac{1}{4} + \tfrac{1}{2}it)] - \tfrac{1}{2}t \ln \pi. \end{aligned}$$

These functions are implemented in *Mathematica*® (Wolfram Research, Champaign, IL) as `RiemannSiegelZ[z]` and `RiemannSiegelTheta[z]`, illustrated above.

## Riemann Space

see METRIC SPACE

## Riemann Sphere

A 1-D COMPLEX MANIFOLD  $\mathbb{C}^*$ , which is the one-point compactification of the COMPLEX numbers  $\mathbb{C} \cup \{\infty\}$ , together with two charts. For all points in the COMPLEX PLANE, the chart is the IDENTITY MAP from the SPHERE (with infinity removed) to the COMPLEX PLANE. For the point at infinity, the chart neighborhood is the sphere (with the ORIGIN removed), and the chart is given by sending infinity to 0 and all other points  $z$  to  $1/z$ .

## Riemann-Stieltjes Integral

see STIELTJES INTEGRAL

## Riemann Sum

Let a CLOSED INTERVAL  $[a, b]$  be partitioned by points  $a < x_1 < x_2 < \dots < x_{n-1} < b$ , the lengths of the resulting intervals between the points are denoted  $\Delta x_1, \Delta x_2, \dots, \Delta x_n$ . Then the quantity

$$\sum_{k=1}^n f(x_k^*) \Delta x_k$$

is called a Riemann sum for a given function  $f(x)$  and partition. The value  $\max \Delta x_k$  is called the MESH SIZE of the partition. If the LIMIT  $\max \Delta x_k \rightarrow 0$  exists, this limit is known as the Riemann INTEGRAL of  $f(x)$  over the interval  $[a, b]$ . The shaded areas in the above plots show the LOWER and UPPER SUMS for a constant MESH SIZE.

see also LOWER SUM, RIEMANN INTEGRAL, UPPER SUM

## Riemann Surface

The Riemann surface  $S$  of the ALGEBRAIC FUNCTION FIELD  $K$  is the set of nontrivial discrete valuations on  $K$ . Here, the set  $S$  corresponds to the IDEALS of the RING  $A$  of INTEGERS of  $K$  over  $\mathbb{C}(z)$ . ( $A$  consists of the elements of  $K$  that are ROOTS of MONIC POLYNOMIALS over  $\mathbb{C}[z]$ .)

### Riemann Tensor

A TENSOR sometimes known as the RIEMANN-CHRISTOFFEL TENSOR. Let

$$\tilde{D}_s \equiv \frac{\partial}{\partial x^s} - \sum_l \left\{ \begin{matrix} s & u \\ l & \end{matrix} \right\} \quad (1)$$

where the quantity inside the  $\left\{ \begin{matrix} s & u \\ l & \end{matrix} \right\}$  is a CHRISTOFFEL SYMBOL OF THE SECOND KIND. Then

$$R_{pqrs} \equiv \tilde{D}_q \left\{ \begin{matrix} p & r \\ s & \end{matrix} \right\} - \tilde{D}_r \left\{ \begin{matrix} p & q \\ s & \end{matrix} \right\}. \quad (2)$$

Broken down into its simplest decomposition in  $N$ -D,

$$R_{\lambda\mu\nu\kappa} = \frac{1}{N-2} (g_{\lambda\nu} R_{\mu\kappa} - g_{\lambda\kappa} R_{\mu\nu} - g_{\mu\nu} R_{\lambda\kappa} + g_{\mu\kappa} R_{\lambda\nu}) - \frac{R}{(N-1)(N-2)} (g_{\lambda\nu} g_{\mu\kappa} - g_{\lambda\kappa} g_{\mu\nu}) + C_{\lambda\mu\nu\kappa}. \quad (3)$$

Here,  $R_{\mu\nu}$  is the RICCI TENSOR,  $R$  is the CURVATURE SCALAR, and  $C_{\lambda\mu\nu\kappa}$  is the WEYL TENSOR. In terms of the JACOBI TENSOR  $J^\mu_{\nu\alpha\beta}$ ,

$$R^\mu_{\alpha\nu\beta} = \frac{2}{3} (J^\mu_{\nu\alpha\beta} - J^\mu_{\beta\alpha\nu}). \quad (4)$$

The Riemann tensor is the only tensor that can be constructed from the METRIC TENSOR and its first and second derivatives,

$$R^\alpha_{\beta\gamma\delta} = \Gamma^\alpha_{\beta\delta,\gamma} - \Gamma^\alpha_{\beta\gamma,\delta} + \Gamma^\alpha_{\mu\gamma} \Gamma^\mu_{\beta\delta} - \Gamma^\alpha_{\mu\delta} \Gamma^\mu_{\beta\gamma} - \Gamma^\alpha_{\beta\mu} c_{\gamma\delta}^\mu, \quad (5)$$

where  $\Gamma$  are CONNECTION COEFFICIENTS and  $c$  are COMMUTATION COEFFICIENTS. The number of independent coordinates in  $n$ -D is

$$C_n \equiv \frac{1}{12} n^2 (n^2 - 1), \quad (6)$$

and the number of SCALARS which can be constructed from  $R_{\lambda\mu\nu\kappa}$  and  $g_{\mu\nu}$  is

$$S_n \equiv \begin{cases} 1 & \text{for } n = 2 \\ \frac{1}{12} n(n-1)(n-2)(n+3) & \text{for } n = 1, n > 2. \end{cases} \quad (7)$$

In 1-D,  $R_{1111} = 0$ .

$n$	$C_n$	$S_n$
1	0	0
2	1	1
3	6	3
4	20	14

### Riemann Theta Function

Let the IMAGINARY PART of a  $g \times g$  MATRIX  $F$  be POSITIVE DEFINITE, and  $\mathbf{m} = (m_1, \dots, m_g)$  be a row VECTOR with coefficients in  $\mathbb{Z}$ . Then the Riemann theta function is defined by

$$\vartheta(u) = \sum_{\mathbf{m}} \exp[2\pi i(\mathbf{m}^T u + \frac{1}{2} F^T \mathbf{m})].$$

### Riemann Weighted Prime-Power Counting Function

The Riemann weighted prime-power counting function is defined by

$$J_2(x) \equiv \begin{cases} \pi(x) + \frac{1}{2}\pi(x^{1/2}) + \frac{1}{3}\pi(x^{1/3}) + \dots - \frac{1}{2m} & \text{for } p^m \text{ with } p \text{ a prime} \\ \pi(x) + \frac{1}{2}\pi(x^{1/2}) + \frac{1}{3}\pi(x^{1/3}) + \dots & \text{otherwise} \end{cases} \quad (1)$$

$$= \lim_{t \rightarrow \infty} \frac{1}{2\pi i} \int_{2-iT}^{2+iT} \frac{x^s}{s} \ln \zeta(s) ds. \quad (2)$$

The PRIME COUNTING FUNCTION is given in terms of  $J_2(x)$  by

$$\pi(x) = \sum_{n=1}^{\infty} \frac{\mu(n)}{n} J_2(x^{1/n}). \quad (3)$$

The function also satisfies the identity

$$\frac{\ln \zeta(s)}{s} = \int_1^{\infty} J_2(x) x^{-s-1} dx. \quad (4)$$

see also MANGOLDT FUNCTION, PRIME COUNTING FUNCTION, RIEMANN'S FORMULA

### Riemann Xi Function

see XI FUNCTION

### Riemann Zeta Function

The Riemann zeta function can be defined by the integral

$$\zeta(x) \equiv \frac{1}{\Gamma(x)} \int_0^\infty \frac{u^{x-1}}{e^u - 1} du, \quad (1)$$

where  $x > 1$ . If  $x$  is an INTEGER  $n$ , then

$$\frac{u^{n-1}}{e^u - 1} = \frac{e^{-u} u^{n-1}}{1 - e^{-u}} = e^{-u} u^{n-1} \sum_{k=1}^{\infty} e^{-ku} u^{n-1}, \quad (2)$$

so

$$\int_0^\infty \frac{u^{n-1}}{e^u - 1} du = \sum_{k=1}^{\infty} \int_0^\infty e^{-ku} u^{n-1} du. \quad (3)$$

Let  $y \equiv ku$ , then  $dy = k du$  and

$$\begin{aligned} \zeta(n) &= \frac{1}{\Gamma(n)} \sum_{k=1}^{\infty} \int_0^\infty e^{-ku} u^{n-1} du \\ &= \frac{1}{\Gamma(n)} \sum_{k=1}^{\infty} \int_0^\infty e^{-y} \left(\frac{y}{k}\right)^{n-1} \frac{dy}{k} \\ &= \frac{1}{\Gamma(n)} \sum_{k=1}^{\infty} \frac{1}{k^n} \int_0^\infty e^{-y} y^{n-1} dy, \end{aligned} \quad (4)$$

where  $\Gamma(n)$  is the GAMMA FUNCTION. Integrating the final expression in (4) gives  $\Gamma(n)$ , which cancels the factor  $1/\Gamma(n)$  and gives the most common form of the Riemann zeta function,

$$\zeta(n) = \sum_{k=1}^{\infty} \frac{1}{k^n}. \quad (5)$$

At  $n = 1$ , the zeta function reduces to the HARMONIC SERIES (which diverges), and therefore has a singularity. In the COMPLEX PLANE, trivial zeros occur at  $-2, -4, -6, \dots$ , and nontrivial zeros at

$$s \equiv \sigma + it \quad (6)$$

for  $0 \leq \sigma \leq 1$ . The figures below show the structure of  $\zeta(z)$  by plotting  $|\zeta(z)|$  and  $1/|\zeta(z)|$ .

The RIEMANN HYPOTHESIS asserts that the nontrivial ROOTS of  $\zeta(s)$  all have REAL PART  $\sigma = \Re[s] = 1/2$ , a line called the "CRITICAL STRIP." This is known to be true for the first  $1.5 \times 10^{12}$  roots (Brent *et al.* 1979). The above plot shows  $|\zeta(1/2 + it)|$  for  $t$  between 0 and 60. As can be seen, the first few nontrivial zeros occur at  $t = 14.134725, 21.022040, 25.010858, 30.424876, 32.935062, 37.586178, \dots$  (Wagon 1991, pp. 361–362 and 367–368).

The Riemann zeta function can also be defined in terms of MULTIPLE INTEGRALS by

$$\zeta(n) = \underbrace{\int_0^1 \cdots \int_0^1}_{n} \frac{\prod_{i=1}^n dx_i}{1 - \prod_{i=1}^n x_i}. \quad (7)$$

The Riemann zeta function can be split up into

$$\zeta\left(\frac{1}{2} + it\right) = z(t)e^{-i\vartheta(t)}, \quad (8)$$

where  $z(t)$  and  $\vartheta(t)$  are the RIEMANN-SIEGEL FUNCTIONS. An additional identity is

$$\lim_{s \rightarrow 1} \zeta(s) - \frac{1}{s-1} = \gamma, \quad (9)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT.

The Riemann zeta function is related to the DIRICHLET LAMBDA FUNCTION  $\lambda(\nu)$  and DIRICHLET ETA FUNCTION  $\eta(\nu)$  by

$$\frac{\zeta(\nu)}{2^\nu} = \frac{\lambda(\nu)}{2^\nu - 1} = \frac{\eta(\nu)}{2^\nu - 2} \quad (10)$$

and

$$\zeta(\nu) + \eta(\nu) = 2\lambda(\nu) \quad (11)$$

(Spanier and Oldham 1987). It is related to the LIOUVILLE FUNCTION  $\lambda(n)$  by

$$\frac{\zeta(2s)}{\zeta(s)} = \sum_{n=1}^{\infty} \frac{\lambda(n)}{n^s} \quad (12)$$

(Lehman 1960, Hardy and Wright 1979). Furthermore,

$$\frac{\zeta^2(s)}{\zeta(2s)} = \sum_{n=1}^{\infty} \frac{2^{\omega(n)}}{n^s}, \quad (13)$$

where  $\omega(n) = \sigma_0(n)$  is the number of different prime factors of  $n$  (Hardy and Wright 1979).

A generalized Riemann zeta function  $\zeta(s, a)$  known as the HURWITZ ZETA FUNCTION can also be defined such that

$$\zeta(s) \equiv \zeta(s, 0). \quad (14)$$

The Riemann zeta function may be computed analytically for EVEN  $n$  using either CONTOUR INTEGRATION or PARSEVAL'S THEOREM with the appropriate FOURIER SERIES. An interesting formula involving the product of PRIMES was first discovered by Euler in 1737,

$$\begin{aligned} \zeta(x)(1-2^{-x}) &= \left(1 + \frac{1}{2^x} + \frac{1}{3^x} + \dots\right) \left(1 - \frac{1}{2^x}\right) \\ &= \left(1 + \frac{1}{2^x} + \frac{1}{3^x} + \dots\right) - \left(\frac{1}{2^x} + \frac{1}{4^x} + \frac{1}{6^x} + \dots\right) \end{aligned} \quad (15)$$

$$\begin{aligned} \zeta(x)(1-2^{-x})(1-3^{-x}) &= \left(1 + \frac{1}{2^x} + \frac{1}{3^x} + \frac{1}{5^x} + \frac{1}{7^x} + \dots\right) - \left(\frac{1}{3^x} + \frac{1}{9^x} + \frac{1}{15^x} + \dots\right) \end{aligned} \quad (16)$$

$$\begin{aligned} \zeta(x)(1-2^{-x})(1-3^{-x}) \dots (1-p^{-x}) \dots \\ = \zeta(x) \prod_{n=2}^{\infty} (1-p^{-x}) = 1. \end{aligned} \quad (17)$$

Here, each subsequent multiplication by the next PRIME  $p$  leaves only terms which are POWERS of  $p^{-x}$ . Therefore,

$$\zeta(x) = \left[ \prod_{p=2}^{\infty} (1-p^{-x}) \right]^{-1}, \quad (18)$$

where  $p$  runs over all PRIMES. Euler's product formula can also be written

$$\zeta(s) = (1-2^{-s})^{-1} \prod_{\substack{q \equiv 1 \\ (\text{mod } 4)}} (1-q^{-s})^{-1} \prod_{\substack{r \equiv 3 \\ (\text{mod } 4)}} (1-r^{-s})^{-1}. \quad (19)$$

A few sum identities involving  $\zeta(n)$  are

$$\sum_{n=2}^{\infty} [\zeta(n) - 1] = 1 \quad (20)$$

$$\sum_{n=2}^{\infty} (-1)^n [\zeta(n) - 1] = \frac{1}{2}. \quad (21)$$

The Riemann zeta function is related to the GAMMA FUNCTION  $\Gamma(z)$  by

$$\Gamma\left(\frac{s}{2}\right) \pi^{-s/2} \zeta(s) = \Gamma\left(\frac{1-s}{2}\right) \pi^{-(1-s)/2} \zeta(1-s). \quad (22)$$

$\zeta(n)$  was proved to be transcendental for all even  $n$  by Euler. Apéry (1979) proved  $\zeta(3)$  to be IRRATIONAL with

the aid of the  $k^{-3}$  sum formula below. As a result,  $\zeta(3)$  is sometimes called APÉRY'S CONSTANT.

$$\zeta(2) = 3 \sum_{k=1}^{\infty} \frac{1}{k^2 \binom{2k}{k}} \quad (23)$$

$$\zeta(3) = \frac{5}{2} \sum_{k=1}^{\infty} \frac{(-1)^{k-1}}{k^3 \binom{2k}{k}} \quad (24)$$

$$\zeta(4) = \frac{36}{17} \sum_{k=1}^{\infty} \frac{1}{k^4 \binom{2k}{k}} \quad (25)$$

(Guy 1994, p. 257). A relation of the form

$$\zeta(5) = Z_5 \sum_{k=1}^{\infty} \frac{(-1)^{k-1}}{k^5 \binom{2k}{k}} \quad (26)$$

has been searched for with  $Z_5$  a RATIONAL or ALGEBRAIC NUMBER, but if  $Z_5$  is a ROOT of a POLYNOMIAL of degree 25 or less, then the Euclidean norm of the coefficients must be larger than  $2 \times 10^{37}$  (Bailey, Bailey and Plouffe). Therefore, no such sums are known for  $\zeta(n)$  are known for  $n \geq 5$ .

The zeta function is defined for  $\Re[s] > 1$ , but can be analytically continued to  $\Re[s] > 0$  as follows

$$\begin{aligned} \sum_{n=1}^{\infty} (-1)^n n^{-s} + \sum_{n=1}^{\infty} n^{-s} &= 2 \sum_{n=2,4,\dots}^{\infty} n^{-s} \\ &= 2 \sum_{k=1}^{\infty} (2k)^{-s} = 2^{1-s} \sum_{k=1}^{\infty} k^{-s} \end{aligned} \quad (27)$$

$$\sum_{n=1}^{\infty} (-1)^n n^{-s} + \zeta(s) = 2^{1-s} \zeta(s) \quad (28)$$

$$\zeta(s) = \frac{1}{1-2^{1-s}} \sum_{n=1}^{\infty} (-1)^n n^{-s}. \quad (29)$$

The DERIVATIVE of the Riemann zeta function is defined by

$$\zeta'(s) = -s \sum_{k=1}^{\infty} k^{-s} \ln k = - \sum_{k=2}^{\infty} \frac{\ln k}{k^s}. \quad (30)$$

As  $s \rightarrow 0$ ,

$$\zeta'(0) = -\frac{1}{2} \ln(2\pi). \quad (31)$$

For EVEN  $n = 2k$ ,

$$\zeta(n) = \frac{2^{n-1} |B_n| \pi^n}{n!}, \quad (32)$$

where  $B_n$  is a BERNOULLI NUMBER. Another intimate connection with the BERNOULLI NUMBERS is provided by

$$B_n = (-1)^{n+1} n \zeta(1-n). \quad (33)$$

No analytic form for  $\zeta(n)$  is known for ODD  $n \equiv 2k + 1$ , but  $\zeta(2k + 1)$  can be expressed as the sum limit

$$\zeta(2k + 1) = \left(\frac{1}{2}\pi\right)^{2k+1} \lim_{t \rightarrow \infty} \frac{1}{t^{2k+1}} \sum_{i=1}^{\infty} \left[ \cot\left(\frac{i}{2t+1}\right) \right]^{2k+1} \quad (34)$$

(Stark 1974). The values for the first few integral arguments are

$$\begin{aligned} \zeta(0) &\equiv -\frac{1}{2} \\ \zeta(1) &= \infty \\ \zeta(2) &= \frac{\pi^2}{6} \\ \zeta(3) &= 1.2020569032\dots \\ \zeta(4) &= \frac{\pi^4}{90} \\ \zeta(5) &= 1.0369277551\dots \\ \zeta(6) &= \frac{\pi^6}{945} \\ \zeta(7) &= 1.0083492774\dots \\ \zeta(8) &= \frac{\pi^8}{9450} \\ \zeta(9) &= 1.0020083928\dots \\ \zeta(10) &= \frac{\pi^{10}}{93,555} \end{aligned}$$

Euler gave  $\zeta(2)$  to  $\zeta(26)$  for EVEN  $n$ , and Stieltjes (1993) determined the values of  $\zeta(2), \dots, \zeta(70)$  to 30 digits of accuracy in 1887. The denominators of  $\zeta(2n)$  for  $n = 1, 2, \dots$  are 6, 90, 945, 9450, 93555, 638512875, ... (Sloane's A002432).

Using the LLL ALGORITHM, Plouffe (inspired by Zucker 1979, Zucker 1984, and Berndt 1988) has found some beautiful infinite sums for  $\zeta(n)$  with ODD  $n$ . Let

$$S_{\pm}(n) \equiv \sum_{k=1}^{\infty} \frac{1}{k^n(e^{2\pi k} \pm 1)}, \quad (35)$$

then

$$\zeta(3) = \frac{7}{180}\pi^3 - 2S_-(3) \quad (36)$$

$$\zeta(5) = \frac{1}{294}\pi^5 - \frac{72}{35}S_-(5) - \frac{2}{35}S_+(5) \quad (37)$$

$$\zeta(7) = \frac{19}{56700}\pi^7 - 2S_-(7) \quad (38)$$

$$\zeta(9) = \frac{125}{3704778}\pi^9 - \frac{992}{495}S_-(9) - \frac{2}{495}S_+(9) \quad (39)$$

$$\zeta(11) = \frac{1453}{425675250}\pi^{11} - 2S_-(11) \quad (40)$$

$$\zeta(13) = \frac{89}{257432175}\pi^{13} - \frac{16512}{8255}S_-(13) - \frac{2}{8255}S_+(13) \quad (41)$$

$$\zeta(15) = \frac{13687}{390769879500}\pi^{15} - 2S_-(15) \quad (42)$$

$$\zeta(17) = \frac{397549}{112024529867250}\pi^{17} - \frac{261632}{130815}S_-(17) - \frac{2}{130815}S_+(17) \quad (43)$$

$$\zeta(19) = \frac{7708537}{21438612514068750}\pi^{19} - 2S_-(19) \quad (44)$$

$$\zeta(21) = \frac{68529640373}{1881063815762259253125}\pi^{21} - \frac{4196352}{2098175}S_-(21) - \frac{2}{2098175}S_+(21) \quad (45)$$

The inverse of the RIEMANN ZETA FUNCTION  $1/\zeta(p)$  is the asymptotic density of  $p$ th-powerfree numbers (i.e., SQUAREFREE numbers, CUBEFREE numbers, etc.). The following table gives the number  $Q_p(n)$  of  $p$ th-powerfree numbers  $\leq n$  for several values of  $n$ .

$p$	$1/\zeta(p)$	10	100	$10^3$	$10^4$	$10^5$	$10^6$
2	0.607927	7	61	608	6083	60794	607926
3	0.831907	9	85	833	8319	83190	831910
4	0.923938	10	93	925	9240	92395	923939
5	0.964387	10	97	965	9645	96440	964388
6	0.982953	10	99	984	9831	98297	982954

The value for  $\zeta(2)$  can be found using a number of different techniques (Apostol 1983, Choe 1987, Giesy 1972, Holme 1970, Kimble 1987, Knopp and Schur 1918, Kortram 1996, Matsuoka 1961, Papadimitriou 1973, Simmons 1992, Stark 1969, Stark 1970, Yaglom and Yaglom 1987). The problem of finding this value analytically is sometimes known as the BASLER PROBLEM (Castellanos 1988). Yaglom and Yaglom (1987), Holme (1970), and Papadimitriou (1973) all derive the result from DE MOIVRE'S IDENTITY or related identities.

Consider the FOURIER SERIES of  $f(x) = x^{2n}$

$$f(x) = \frac{1}{2}a_0 + \sum_{m=1}^{\infty} a_m \cos(mx) + \sum_{m=1}^{\infty} b_m \sin(mx), \quad (46)$$

which has coefficients given by

$$\begin{aligned} a_0 &= \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx = \frac{2}{\pi} \int_0^{\pi} x^{2n} dx \\ &= \frac{2}{\pi} \left[ \frac{x^{2n+1}}{2n+1} \right]_0^{\pi} = \frac{2\pi^{2n}}{2n+1} \end{aligned} \quad (47)$$

$$\begin{aligned} a_m &= \frac{1}{\pi} \int_{-\pi}^{\pi} x^{2n} \cos(mx) dx \\ &= \frac{2}{\pi} \int_0^{\pi} x^{2n} \cos(mx) dx \end{aligned} \quad (48)$$

$$b_m = \frac{1}{\pi} \int_{-\pi}^{\pi} x^{2n} \sin(mx) dx = 0, \quad (49)$$

where the latter is true since the integrand is ODD. Therefore, the FOURIER SERIES is given explicitly by

$$x^{2n} = \frac{\pi^{2n}}{2n+1} + \sum_{m=1}^{\infty} a_m \cos(mx). \quad (50)$$

Now,  $a_m$  is given by the COSINE INTEGRAL

$$a_m = \frac{2}{\pi} (-1)^{n+1} (2n)! \left[ \sin(mx) \sum_{k=0}^n \frac{(-1)^k}{(2k)! m^{2n-2k+1}} x^{2k} + \cos(mx) \sum_{k=1}^n \frac{(-1)^{k+1}}{(2k-3)! m^{2n-2k+2}} x^{2k-1} \right]_0^\pi. \quad (51)$$

But  $\cos(m\pi) = (-1)^m$ , and  $\sin(m\pi) = \sin 0 = 0$ , so

$$\begin{aligned} a_m &= \frac{2}{\pi} (-1)^{n+1} (2n)! (-1)^m \sum_{k=1}^n \frac{(-1)^{k+1}}{(2k-3)! m^{2n-2k+2}} \pi^{2k-1} \\ &= (-1)^{m+n} 2(2n)! \sum_{k=1}^n \frac{(-1)^k}{(2k-3)! m^{2n-2k+2}} \pi^{2k-2}. \end{aligned} \quad (52)$$

Now, if  $n = 1$ ,

$$\begin{aligned} a_m &= (-1)^{m+1} 2(2!) \sum_{k=1}^1 \frac{(-1)^k}{(2k-3)! m^{4-2k}} \pi^{2k-2} \\ &= 4(-1)^{m+1} \frac{(-1)}{(-1)! m^2} \pi^0 = \frac{4(-1)^m}{m^2}, \end{aligned} \quad (53)$$

so the FOURIER SERIES is

$$x^2 = \frac{\pi^2}{3} + 4 \sum_{m=1}^{\infty} \frac{(-1)^m \cos(mx)}{m^2}. \quad (54)$$

Letting  $x \equiv \pi$  gives  $\cos(m\pi) = (-1)^m$ , so

$$\pi^2 = \frac{\pi^2}{3} + 4 \sum_{m=1}^{\infty} \frac{1}{m^2}, \quad (55)$$

and we have

$$\zeta(2) = \sum_{m=1}^{\infty} \frac{1}{m^2} = \frac{\pi^2}{6}. \quad (56)$$

Higher values of  $n$  can be obtained by finding  $a_m$  and proceeding as above.

The value  $\zeta(2)$  can also be found simply using the ROOT LINEAR COEFFICIENT THEOREM. Consider the equation  $\sin z = 0$  and expand  $\sin$  in a MACLAURIN SERIES

$$\sin z = z - \frac{z^3}{3!} + \frac{z^5}{5!} - \dots = 0 \quad (57)$$

$$0 = 1 - \frac{z^2}{3!} + \frac{z^4}{5!} - \dots = 1 - \frac{w}{3!} + \frac{w^2}{5!} - \dots, \quad (58)$$

where  $w \equiv z^2$ . But the zeros of  $\sin(z)$  occur at  $\pi, 2\pi, 3\pi, \dots$ , so the zeros of  $\sin w = \sin \sqrt{z}$  occur at  $\pi^2, (2\pi)^2, \dots$ . Therefore, the sum of the roots equals the COEFFICIENT of the leading term

$$\frac{1}{\pi^2} + \frac{1}{(2\pi)^2} + \frac{1}{(3\pi)^2} + \dots = \frac{1}{3!} = \frac{1}{6}, \quad (59)$$

which can be rearranged to yield

$$\zeta(2) = \frac{\pi^2}{6}. \quad (60)$$

Yet another derivation (Simmons 1992) evaluates the integral using the integral

$$\begin{aligned} I &= \int_0^1 \int_0^1 \frac{dx dy}{1-xy} = \int_0^1 \int_0^1 (1 + xy + x^2 y^2 + \dots) dx dy \\ &= \int_0^1 [(x + \frac{1}{2} x^2 y + \frac{1}{3} x^3 y^2 + \dots)]_0^1 dy \\ &= \int_0^1 (1 + \frac{1}{2} y + \frac{1}{3} y^2 + \dots) dy \\ &= \left[ y + \frac{y^2}{2^2} + \frac{y^3}{3^2} + \dots \right]_0^1 = 1 + \frac{1}{2^2} + \frac{1}{3^2} + \dots \end{aligned} \quad (61)$$

To evaluate the integral, rotate the coordinate system by  $\pi/4$  so

$$x = u \cos \theta - v \sin \theta = \frac{1}{2} \sqrt{2} (u - v) \quad (62)$$

$$y = u \sin \theta + v \cos \theta = \frac{1}{2} \sqrt{2} (u + v) \quad (63)$$

and

$$xy = \frac{1}{2} (u^2 - v^2) \quad (64)$$

$$1 - xy = \frac{1}{2} (2 - u^2 + v^2). \quad (65)$$

Then

$$\begin{aligned} I &= 4 \int_0^{\sqrt{2}/2} \int_0^u \frac{du dv}{2 - u^2 + v^2} \\ &\quad + 4 \int_{\sqrt{2}/2}^{\sqrt{2}} \int_0^{\sqrt{2}-u} \frac{du dv}{2 - u^2 + v^2} \equiv I_1 + I_2. \end{aligned} \quad (66)$$

Now compute the integrals  $I_1$  and  $I_2$ .

$$\begin{aligned} I_1 &= 4 \int_0^{\sqrt{2}/2} \left[ \int_0^u \frac{dv}{2 - u^2 + v^2} \right] du \\ &= 4 \int_0^{\sqrt{2}/2} \left[ \frac{1}{\sqrt{2-u^2}} \tan^{-1} \left( \frac{v}{\sqrt{2-u^2}} \right) \right]_0^u du \\ &= 4 \int_0^{\sqrt{2}/2} \frac{1}{\sqrt{2-u^2}} \tan^{-1} \left( \frac{u}{\sqrt{2-u^2}} \right) du. \end{aligned} \quad (67)$$

Make the substitution

$$u = \sqrt{2} \sin \theta \quad (68)$$

$$\sqrt{2-u^2} = \sqrt{2} \cos \theta \quad (69)$$

$$du = \sqrt{2} \cos \theta d\theta, \quad (70)$$

so

$$\tan^{-1} \left( \frac{u}{\sqrt{2-u^2}} \right) = \tan^{-1} \left( \frac{\sqrt{2} \sin \theta}{\sqrt{2} \cos \theta} \right) = \theta \quad (71)$$

and

$$I_1 = 4 \int_0^{\pi/6} \frac{1}{\sqrt{2} \cos \theta} \theta \sqrt{2} \cos \theta d\theta = 2[\theta^2]_0^{\pi/6} = \frac{\pi^2}{18}. \quad (72)$$

$I_2$  can also be computed analytically,

$$\begin{aligned} I_2 &= 4 \int_{\sqrt{2}/2}^{\sqrt{2}} \left[ \int_0^{\sqrt{2}-u} \frac{dv}{2-u^2+v^2} \right] du \\ &= 4 \int_{\sqrt{2}/2}^{\sqrt{2}} \left[ \frac{1}{\sqrt{2-u^2}} \tan^{-1} \left( \frac{v}{\sqrt{2-u^2}} \right) \right]_0^{\sqrt{2}-u} du \\ &= 4 \int_{\sqrt{2}/2}^{\sqrt{2}} \frac{1}{\sqrt{2-u^2}} \tan^{-1} \left( \frac{\sqrt{2}-u}{\sqrt{2-u^2}} \right) du. \end{aligned} \quad (73)$$

But

$$\begin{aligned} \tan^{-1} \left( \frac{\sqrt{2}-u}{\sqrt{2-u^2}} \right) &= \tan^{-1} \left( \frac{\sqrt{2}-\sqrt{2} \sin \theta}{\sqrt{2} \cos \theta} \right) \\ &= \tan^{-1} \left( \frac{1-\sin \theta}{\cos \theta} \right) = \tan^{-1} \left( \frac{\cos \theta}{1+\sin \theta} \right) \\ &= \tan^{-1} \left[ \frac{\sin(\frac{1}{2}\pi - \theta)}{1 + \cos(\frac{1}{2}\pi - \theta)} \right] \\ &= \tan^{-1} \left\{ \frac{2 \sin[\frac{1}{2}(\frac{1}{2}\pi - \theta)] \cos[\frac{1}{2}(\frac{1}{2}\pi - \theta)]}{2 \cos^2[\frac{1}{2}(\frac{1}{2}\pi - \theta)]} \right\} \\ &= \frac{1}{2}(\frac{1}{2}\pi - \theta), \end{aligned} \quad (74)$$

so

$$\begin{aligned} I_2 &= 4 \int_{\pi/6}^{\pi/2} \frac{1}{\sqrt{2} \cos \theta} (\frac{1}{4}\pi - \frac{1}{2}\theta) \sqrt{2} \cos \theta d\theta \\ &= 4 \left[ \frac{1}{4}\pi\theta - \frac{1}{4}\theta^2 \right]_{\pi/6}^{\pi/2} \\ &= 4 \left[ \left( \frac{\pi^2}{8} - \frac{\pi^2}{16} \right) - \left( \frac{\pi^2}{24} - \frac{\pi^2}{144} \right) \right] = \frac{\pi^2}{9}. \end{aligned} \quad (75)$$

Combining  $I_1$  and  $I_2$  gives

$$\zeta(2) = I_1 + I_2 = \frac{\pi^2}{18} + \frac{\pi^2}{9} = \frac{\pi^2}{6}. \quad (76)$$

## Riemannian Geometry

The study of MANIFOLDS having a complete RIEMANNIAN METRIC. Riemannian geometry is a general space based on the LINE ELEMENT

$$ds = F(x^1, \dots, x^n; dx^1, \dots, dx^n),$$

with  $F(x, y) > 0$  for  $y \neq 0$  a function on the TANGENT BUNDLE  $TM$ . In addition,  $F$  is homogeneous of degree 1 in  $y$  and of the form

$$F^2 = g_{ij}(x) dx^i dx^j$$

(Chern 1996). If this restriction is dropped, the resulting geometry is called FINSLER GEOMETRY.

## Riemannian Geometry (Non-Euclidean)

see ELLIPTIC GEOMETRY

## Riemannian Manifold

A MANIFOLD possessing a METRIC TENSOR. For a complete Riemannian manifold, the METRIC  $d(x, y)$  is defined as the length of the shortest curve (GEODESIC) between  $x$  and  $y$ .

see also BISHOP'S INEQUALITY, CHEEGER'S FINITENESS THEOREM

## Riemannian Metric

Suppose for every point  $x$  in a COMPACT MANIFOLD  $M$ , an INNER PRODUCT  $\langle \cdot, \cdot \rangle_x$  is defined on a TANGENT SPACE  $T_x M$  of  $M$  at  $x$ . Then the collection of all these INNER PRODUCTS is called the Riemannian metric. In 1870, Christoffel and Lipschitz showed how to decide when two Riemannian metrics differ by only a coordinate transformation.

see also COMPACT MANIFOLD, LINE ELEMENT, METRIC TENSOR

## Riesel Number

There exist infinitely many ODD INTEGERS  $k$  such that  $k \cdot 2^n - 1$  is COMPOSITE for every  $n \geq 1$ . Numbers  $k$  with this property are called RIESEL NUMBERS, and analogous numbers with the minus sign replaced by a plus are called SIERPIŃSKI NUMBERS OF THE SECOND KIND. The smallest known Riesel number is  $k = 509,203$ , but there remain 963 smaller candidates (the smallest of which is 659) which generate only composite numbers for all  $n$  which have been checked (Ribenoim 1996, p. 358).

Let  $a(k)$  be smallest  $n$  for which  $(2k - 1) \cdot 2^n - 1$  is PRIME, then the first few values are 2, 0, 2, 1, 1, 2, 3, 1, 2, 1, 1, 4, 3, 1, 4, 1, 2, 2, 1, 3, 2, 7, ... (Sloane's A046069), and second smallest  $n$  are 3, 1, 4, 5, 3, 26, 7, 2, 4, 3, 2, 6, 9, 2, 16, 5, 3, 6, 2553, ... (Sloane's A046070).

### Riesz-Fischer Theorem

A function is  $L_2$ - (square-) integrable IFF its FOURIER SERIES is  $L_2$ -convergent. The application of this theorem requires use of the LEBESGUE INTEGRAL.

see also LEBESGUE INTEGRAL

### Riesz Representation Theorem

Let  $f$  be a bounded linear FUNCTIONAL on a HILBERT SPACE  $H$ . Then there exists exactly one  $x_0 \in H$  such that  $f(x) = \langle x, x_0 \rangle$  for all  $x \in H$ . Also,  $\|f\| = \|x_0\|$ .

see also FUNCTIONAL, HILBERT SPACE

### Riesz's Theorem

Every continuous linear functional  $U[f]$  for  $f \in C[a, b]$  can be expressed as a STIELTJES INTEGRAL

$$U[f] = \int_a^b f(x) dw(x),$$

where  $w(x)$  is determined by  $U$  and is of bounded variation on  $[a, b]$ .

see also STIELTJES INTEGRAL

### Riffle Shuffle

A SHUFFLE, also called a FARO SHUFFLE, in which a deck of  $2n$  cards is divided into two HALVES which are then alternatively interleaved from the left and right hands (an "in-shuffle") or from the right and left hands (an "out-shuffle"). Using an "in-shuffle," a deck originally arranged as 1 2 3 4 5 6 7 8 would become 5 1 6 2 7 3 8 4. Using an "out-shuffle," the deck order would become 1 5 2 6 3 7 4 8. Riffle shuffles are used in card tricks (Marlo 1958ab, Adler 1973), and also in the theory of parallel processing (Stone 1971, Chen *et al.* 1981).

In general, card  $k$  moves to the position originally occupied by the  $2k$ th card (mod  $2n + 1$ ). Therefore, in-shuffling  $2n$  cards  $2n$  times (where  $2n + 1$  is PRIME) results in the original card order. Similarly, out-shuffling  $2n$  cards  $2n - 2$  times (where  $2n - 1$  is PRIME) results in the original order (Diaconis *et al.* 1983, Conway and Guy 1996). Amazingly, this means that an ordinary deck of 52 cards is returned to its original order after 8 out-shuffles.

Morris (1994) further discusses aspects of the perfect riffle shuffle (in which the deck is cut exactly in half and cards are perfectly interlaced). Ramnath and Scully (1996) give an algorithm for the shortest sequence of in- and out-shuffles to move a card from arbitrary position  $i$  to position  $j$ . This algorithm works for any deck with an EVEN number of cards and is  $\mathcal{O}(\log n)$ .

### Rigby Points

The PERSPECTIVE CENTERS of the TANGENTIAL and CONTACT TRIANGLES of the inner and outer SODDY POINTS. The Rigby points are given by

$$Ri = I + \frac{4}{3} Ge$$

$$Ri' = I - \frac{4}{3} Ge,$$

where  $I$  is the INCENTER and  $Ge$  is the GERGONNE POINT.

see also CONTACT TRIANGLE, GERGONNE POINT, GRIFFITHS POINTS, INCENTER, OLDKNOW POINTS, SODDY POINTS, TANGENTIAL TRIANGLE

#### References

Oldknow, A. "The Euler-Gergonne-Soddy Triangle of a Triangle." *Amer. Math. Monthly* **103**, 319–329, 1996.

**Right Angle**

An **ANGLE** equal to half the **ANGLE** from one end of a line segment to the other. A right angle is  $\pi/2$  radians or  $90^\circ$ . A **TRIANGLE** containing a right angle is called a **RIGHT TRIANGLE**. However, a **TRIANGLE** cannot contain more than one right angle, since the sum of the two right angles plus the third angle would exceed the  $180^\circ$  total possessed by a **TRIANGLE**.

see also **ACUTE ANGLE**, **OBLIQUE ANGLE**, **OBTUSE ANGLE**, **RIGHT TRIANGLE**, **SEMICIRCLE**, **STRAIGHT ANGLE**, **THALES' THEOREM**

**Right Conoid**

A **RULED SURFACE** is called a right conoid if it can be generated by moving a straight **LINE** intersecting a fixed straight **LINE** such that the **LINES** are always **PERPENDICULAR** (Kreyszig 1991, p. 87). Taking the **PERPENDICULAR** plane as the  $xy$ -plane and the line to be the  $x$ -**AXIS** gives the parametric equations

$$x(u, v) = v \cos \vartheta(u)$$

$$y(u, v) = v \sin \vartheta(u)$$

$$z(u, v) = h(u)$$

(Gray 1993). Taking  $h(u) = 2u$  and  $\vartheta(u) = u$  gives the **HELICOID**.

see also **HELICOID**, **PLÜCKER'S CONOID**, **WALLIS'S CONICAL EDGE**

**Right Hyperbola**

A **HYPERBOLA** for which the **ASYMPTOTES** are **PERPENDICULAR**. This occurs when the **SEMIMAJOR** and **SEMIMINOR AXES** are equal. Taking  $a = b$  in the equation of a **HYPERBOLA** with **SEMIMAJOR AXIS** parallel to the  $x$ -**AXIS** and **SEMIMINOR AXIS** parallel to the  $y$ -**AXIS** (i.e., vertical **DIRECTRIX**),

$$\frac{(x - x_0)^2}{a^2} - \frac{(y - y_0)^2}{b^2} = 1$$

therefore gives

$$(x - x_0)^2 - (y - y_0)^2 = a^2.$$

A special type of right hyperbola is the so-called **RECTANGULAR HYPERBOLA**, which has equation  $xy = ab$ .

see also **HYPERBOLA**, **RECTANGULAR HYPERBOLA**

**Right Line**

see **LINE**

**Right Strophoid**

The **STROPHOID** of a line  $L$  with pole  $O$  not on  $L$  and fixed point  $O'$  being the point where the **PERPENDICULAR** from  $O$  to  $L$  cuts  $L$  is called a right strophoid. It is therefore a general **STROPHOID** with  $a = \pi/2$ .

The right strophoid is given by the Cartesian equation

$$y^2 = \frac{c - x}{c + x} x^2, \quad (1)$$

or the polar equation

$$r = c \cos(2\theta) \sec \theta. \quad (2)$$

The parametric form of the strophoid is

$$x(t) = \frac{1 - t^2}{t^2 + 1} \quad (3)$$

$$y(t) = \frac{t(t^2 - 1)}{t^2 + 1}. \quad (4)$$

The right strophoid has **CURVATURE**

$$\kappa(t) = -\frac{4(1 + 3t^2)}{(1 + 6t^2 + t^4)^{3/2}} \quad (5)$$

and **TANGENTIAL ANGLE**

$$\phi(t) = -2 \tan^{-1} t - \tan^{-1} \left( \frac{2t}{1 + t^2} \right). \quad (6)$$

The right strophoid first appears in work by Isaac Barrow in 1670, although Torricelli describes the curve in his letters around 1645 and Roberval found it as the **LOCUS** of the focus of the conic obtained when the plane cutting the **CONE** rotates about the tangent at its vertex (MacTutor Archive). The **AREA** of the loop is

$$A_{\text{loop}} = \frac{1}{2} c^2 (4 - \pi) \quad (7)$$

(MacTutor Archive).

Let  $C$  be the **CIRCLE** with center at the point where the right strophoid crosses the  $x$ -axis and radius the distance of that point from the origin. Then the right strophoid is invariant under inversion in the **CIRCLE**  $C$  and is therefore an **ANALLAGMATIC CURVE**.

see also **STROPHOID**, **TRISECTRIX**

# Right Strophoid Inverse Curve

The INVERSE CURVE of a right strophoid is the same strophoid.

# Right Triangle

A TRIANGLE with an ANGLE of  $90^\circ$  ( $\pi/2$  radians). The sides  $a$ ,  $b$ , and  $c$  of such a TRIANGLE satisfy the PYTHAGOREAN THEOREM. The largest side is conventionally denoted  $c$  and is called the HYPOTENUSE.

For any three similar shapes on the sides of a right triangle,

$$A_1 + A_2 = A_3, \quad (1)$$

which is equivalent to the PYTHAGOREAN THEOREM. For a right triangle with sides  $a$ ,  $b$ , and HYPOTENUSE  $c$ , let  $r$  be the INRADIUS. Then

$$\frac{1}{2}ab = \frac{1}{2}ra + \frac{1}{2}rb + \frac{1}{2}rc = \frac{1}{2}r(a + b + c). \quad (2)$$

Solving for  $r$  gives

$$r = \frac{ab}{a + b + c}. \quad (3)$$

But any PYTHAGOREAN TRIPLE can be written

$$a = m^2 - n^2 \quad (4)$$

$$b = 2mn \quad (5)$$

$$c = m^2 + n^2, \quad (6)$$

so (5) becomes

$$r = \frac{(m^2 - n^2)2mn}{m^2 - n^2 + 2mn + m^2 + n^2} = n(m - n), \quad (7)$$

which is an INTEGER when  $m$  and  $n$  are integers.

Given a right triangle  $\triangle ABC$ , draw the ALTITUDE  $AH$  from the RIGHT ANGLE  $A$ . Then the triangles  $\triangle AHC$  and  $\triangle BHA$  are similar.

In a right triangle, the MIDPOINT of the HYPOTENUSE is equidistant from the three VERTICES (Dunham 1990). This can be proved as follows. Given  $\triangle ABC$ , let  $M$  be the MIDPOINT of  $AB$  (so that  $AM = BM$ ). Draw  $DM \parallel CA$ , then since  $\triangle BDM$  is similar to  $\triangle BCA$ , it follows that  $BD = DC$ . Since both  $\triangle BDM$  and  $\triangle CDM$  are right triangles and the corresponding legs are equal, the HYPOTENUSES are also equal, so we have  $AM = BM = CM$  and the theorem is proved.

# Rigid

A FRAMEWORK is rigid IFF continuous motion of the points of the configuration maintaining the bar constraints comes from a family of motions of all EUCLIDEAN SPACE which are distance-preserving. A GRAPH  $G$  is (generically)  $d$ -rigid if, for almost all (i.e., an open dense set of) CONFIGURATIONS of  $p$ , the FRAMEWORK  $G(p)$  is rigid in  $\mathbb{R}^d$ .

One of the first results in rigidity theory was the RIGIDITY THEOREM by Cauchy in 1813. Although rigidity problems were of immense interest to engineers, intensive mathematical study of these types of problems has occurred only relatively recently (Connolly 1993, Graver et al. 1993).

### Rigidity Theorem

If the faces of a *convex* POLYHEDRON were made of metal plates and the EDGES were replaced by hinges, the POLYHEDRON would be RIGID. The theorem was stated by Cauchy (1813), although a mistake in this paper went unnoticed for more than 50 years. An example of a *concave* "FLEXIBLE POLYHEDRON" (with 18 triangular faces) for which this is not true was given by Connelly (1978), and a FLEXIBLE POLYHEDRON with only 14 triangular faces was subsequently found by Steffen (Mackenzie 1998).

### Ring

A ring is a set together with two BINARY OPERATORS  $S(+, *)$  satisfying the following conditions:

1. Additive associativity: For all  $a, b, c \in S$ ,  $(a+b)+c = a+(b+c)$ ,
2. Additive commutativity: For all  $a, b \in S$ ,  $a+b = b+a$ ,
3. Additive identity: There exists an element  $0 \in S$  such that for all  $a \in S$ ,  $0+a = a+0 = a$ ,
4. Additive inverse: For every  $a \in S$  there exists  $-a \in S$  such that  $a+(-a) = (-a)+a = 0$ ,
5. Multiplicative associativity: For all  $a, b, c \in S$ ,  $(a*b)*c = a*(b*c)$ ,
6. Left and right distributivity: For all  $a, b, c \in S$ ,  $a*(b+c) = (a*b)+(a*c)$  and  $(b+c)*a = (b*a)+(c*a)$ .

A ring is therefore an ABELIAN GROUP under addition and a SEMIGROUP under multiplication. A ring must contain at least one element, but need not contain a multiplicative identity or be commutative. The number of finite rings of  $n$  elements for  $n = 1, 2, \dots$ , are 1, 2, 2, 11, 2, 4, 2, 52, 11, 4, 2, 22, 2, 4, 4, ... (Sloane's A027623 and A037234; Fletcher 1980). In general, the number of

rings of order  $p^3$  for  $p$  an ODD PRIME is  $3p+50$  and 52 for  $p=2$  (Ballieu 1947, Gilmer and Mott 1973).

A ring with a multiplicative identity is sometimes called a UNIT RING. Fraenkel (1914) gave the first abstract definition of the ring, although this work did not have much impact.

A ring that is COMMUTATIVE under multiplication, has a unit element, and has no divisors of zero is called an INTEGRAL DOMAIN. A ring which is also a COMMUTATIVE multiplication group is called a FIELD. The simplest rings are the INTEGERS  $\mathbb{Z}$ , POLYNOMIALS  $\mathbb{R}[x]$  and  $\mathbb{R}[x, y]$  in one and two variables, and SQUARE  $n \times n$  REAL MATRICES.

Rings which have been investigated and found to be of interest are usually named after one or more of their investigators. This practice unfortunately leads to names which give very little insight into the relevant properties of the associated rings.

### Ring Cyclide

The inversion of a RING TORUS. If the inversion center lies on the torus, then the ring cyclide degenerates to a PARABOLIC RING CYCLIDE.

see also CYCLIDE, PARABOLIC CYCLIDE, RING CYCLIDE, RING TORUS, SPINDLE CYCLIDE, TORUS

## Ring Function

see TOROIDAL FUNCTION

## Ring Torus

One of the three STANDARD TORI given by the parametric equations

$$x = (c + a \cos v) \cos u$$

$$y = (c + a \cos v) \sin u$$

$$z = a \sin v$$

with  $c > a$ . This is the TORUS which is generally meant when the term "torus" is used without qualification. The inversion of a ring torus is a RING CYCLIDE if the INVERSION CENTER does not lie on the torus and a PARABOLIC RING CYCLIDE if it does. The above left figure shows a ring torus, the middle a cutaway, and the right figure shows a CROSS-SECTION of the ring torus through the  $xz$ -plane.

## Robbin's Inequality

If the fourth MOMENT  $\mu_4 \neq 0$ , then

$$P(|\bar{x} - \mu_4| \geq \lambda) \leq \frac{\mu_4 + 3(N - 1)\sigma^4}{N^3\lambda^4},$$

where  $\sigma^2$  is the VARIANCE.

## Robbins Algebra

Building on work of Huntington (1933), Robbins conjectured that the equations for a Robbins algebra, commutativity, associativity, and the ROBBINS EQUATION

$$n(n(x + y) + n(x + n(y))) = x,$$

imply those for a BOOLEAN ALGEBRA. The conjecture was finally proven using a computer (McCune 1997).

**Rogers-Ramanujan Continued Fraction**

see RAMANUJAN CONTINUED FRACTION

### Rogers-Ramanujan Identities

For  $|q| < 1$  and using the NOTATION of the RAMANUJAN THETA FUNCTION, the Rogers-Ramanujan identities are

$$\frac{f(-q^5)}{f(-q, -q^4)} = \sum_{k=0}^{\infty} \frac{q^{k^2}}{(q)_k} \quad (1)$$

$$\frac{f(-q^5)}{f(-q^2, -q^3)} = \sum_{k=0}^{\infty} \frac{q^{k(k+1)}}{(q)_k}, \quad (2)$$

where  $(q)_k$  are  $q$ -SERIES. Written out explicitly (Hardy 1959, p. 13),

$$1 + \frac{q}{1-q} + \frac{q^4}{(1-q)(1-q^2)} + \frac{q^9}{(1-q)(1-q^2)(1-q^3)} + \dots = \frac{1}{(1-q)(1-q^6) \dots (1-q^4)(1-q^9) \dots} \quad (3)$$

$$1 + \frac{q^2}{1-q} + \frac{q^6}{(1-q)(1-q^2)} + \frac{q^{12}}{(1-q)(1-q^2)(1-q^3)} + \dots = \frac{1}{(1-q^2)(1-q^7) \dots (1-q^3)(1-q^8) \dots} \quad (4)$$

The identities can also be written succinctly as

$$1 + \sum_{k=1}^{\infty} \frac{q^{k^2+ak}}{(1-q)(1-q^2) \dots (1-q^k)} = \prod_{j=0}^{\infty} \frac{1}{(1-q^{5j+a+1})(1-q^{5j-a+4})}, \quad (5)$$

where  $a = 0, 1$ .

Other forms of the Rogers-Ramanujan identities include

$$\sum_k \frac{q^{k^2}}{(q; q)_k (q; q)_{n-k}} = \sum_k \frac{(-1)^k q^{(5k^2-k)/2}}{(q; q)_{n-k} (q; q)_{n+k}} \quad (6)$$

and

$$\sum_k \frac{2q^{k^2}}{(q; q)_k (q; q)_{n-k}} = \sum_k \frac{(-1)^k (1+q^k) q^{(5k^2-k)/2}}{(q; q)_{n-k} (q; q)_{n+k}} \quad (7)$$

(Petkovšek et al. 1996).

### Rolle's Theorem

Let  $f$  be differentiable on  $(a, b)$  and continuous on  $[a, b]$ . If  $f(a) = f(b) = 0$ , then there is at least one point  $c \in (a, b)$  where  $f'(c) = 0$ .

see also FIXED POINT THEOREM, MEAN-VALUE THEOREM

### Roman Coefficient

A generalization of the BINOMIAL COEFFICIENT whose NOTATION was suggested by Knuth,

$$\left[ \begin{matrix} n \\ k \end{matrix} \right] = \frac{[n]!}{[k]! [n-k]!}. \quad (1)$$

The above expression is read "Roman  $n$  choose  $k$ ." Whenever the BINOMIAL COEFFICIENT is defined (i.e.,  $n \geq k \geq 0$  or  $k \geq 0 > n$ ), the Roman coefficient agrees with it. However, the Roman coefficients are defined for values for which the BINOMIAL COEFFICIENTS are not, e.g.,

$$\left[ \begin{matrix} n \\ -1 \end{matrix} \right] = \frac{1}{[n+1]} \quad (2)$$

$$\left[ \begin{matrix} 0 \\ k \end{matrix} \right] = \frac{(-1)^{k+(k>0)}}{[k]}, \quad (3)$$

where

$$n < 0 \equiv \begin{cases} 1 & \text{for } n < 0 \\ 0 & \text{for } n \geq 0. \end{cases} \quad (4)$$

The Roman coefficients also satisfy properties like those of the BINOMIAL COEFFICIENT,

$$\left[ \begin{matrix} n \\ k \end{matrix} \right] = \left[ \begin{matrix} n \\ n-k \end{matrix} \right] \quad (5)$$

$$\left[ \begin{matrix} n \\ k \end{matrix} \right] \left[ \begin{matrix} k \\ r \end{matrix} \right] = \left[ \begin{matrix} n \\ r \end{matrix} \right] \left[ \begin{matrix} n-r \\ k-r \end{matrix} \right], \quad (6)$$

an analog of PASCAL'S FORMULA

$$\left[ \begin{matrix} n \\ k \end{matrix} \right] = \left[ \begin{matrix} n-1 \\ k \end{matrix} \right] + \left[ \begin{matrix} n-1 \\ k-1 \end{matrix} \right], \quad (7)$$

and a curious rotation/reflection law due to Knuth

$$(-1)^{k+(k>0)} \begin{bmatrix} -n \\ k-1 \end{bmatrix} = (-1)^{n+(n>0)} \begin{bmatrix} -k \\ n-1 \end{bmatrix} \quad (8)$$

(Roman 1992).

#### References

Roman, S. "The Logarithmic Binomial Formula." *Amer. Math. Monthly* **99**, 641–648, 1992.

### Roman Factorial

$$[n]! \equiv \begin{cases} n! & \text{for } n \geq 0 \\ \frac{(-1)^{-n-1}}{(-n-1)!} & \text{for } n < 0. \end{cases} \quad (1)$$

The Roman factorial arises in the definition of the HARMONIC LOGARITHM and ROMAN COEFFICIENT. It obeys the identities

$$[n]! = [n] [n-1]! \quad (2)$$

$$\frac{[n]!}{[n-k]!} = [n] [n-1] \cdots [n-k+1] \quad (3)$$

$$[n]! [-n-1]! = (-1)^{n+(n<0)}, \quad (4)$$

where

$$[n] \equiv \begin{cases} n & \text{for } n \neq 0 \\ 1 & \text{for } n = 0 \end{cases} \quad (5)$$

and

$$n < 0 \equiv \begin{cases} 1 & \text{for } n < 0 \\ 0 & \text{for } n \geq 0. \end{cases} \quad (6)$$

see also HARMONIC LOGARITHM, HARMONIC NUMBER, ROMAN COEFFICIENT

### Roman Numeral

A system of numerical notations used by the Romans. It is an additive (and subtractive) system in which letters are used to denote certain "base" numbers, and arbitrary numbers are then denoted using combinations of symbols.

Character	Numerical Value
I	1
V	5
X	10
L	50
C	100
D	500
M	1000

For example, the number 1732 would be denoted MDCCXXXII. One additional rule states that, instead of using four symbols to represent a 4, 40, 9, 90, etc., such numbers are instead denoted by preceding the symbol

for 5, 50, 10, 100, etc., with a symbol indicating *subtraction*. For example, 4 is denoted IV, 9 as IX, 40 as XL, etc. However, this rule is generally *not* followed on the faces of clocks, where IIII is usually encountered instead of IV.

Roman numerals are encountered in the release year for movies and occasionally on the numerals on the faces of watches and clocks, but in few other modern instances. They do have the advantage that ADDITION can be done "symbolically" (and without worrying about the "place" of a given DIGIT) by simply combining all the symbols together, grouping, writing groups of 5 Is as V, groups of 2 Vs as X, etc.

### Roman Surface

A QUARTIC NONORIENTABLE SURFACE, also known as the STEINER SURFACE. The Roman surface is one of the three possible surfaces obtained by sewing a MÖBIUS STRIP to the edge of a DISK. The other two are the BOY SURFACE and CROSS-CAP, all of which are homeomorphic to the REAL PROJECTIVE PLANE (Pinkall 1986).

The center point of the Roman surface is an ordinary TRIPLE POINT with  $(\pm 1, 0, 0) = (0, \pm 1, 0) = (0, 0, \pm 1)$ , and the six endpoints of the three lines of self-intersection are singular PINCH POINTS, also known as WHITNEY SINGULARITIES. The Roman surface is essentially six CROSS-CAPS stuck together and contains a double INFINITY of CONICS.

The Roman surface can given by the equation

$$(x^2 + y^2 + z^2 - k^2)^2 = [(z-k)^2 - 2x^2][(z+k)^2 - 2y^2]. \quad (1)$$

Solving for  $z$  gives the pair of equations

$$z = \frac{k(y^2 - x^2) \pm (x^2 - y^2)\sqrt{k^2 - x^2 - y^2}}{2(x^2 + y^2)}. \quad (2)$$

If the surface is rotated by  $45^\circ$  about the  $z$ -AXIS via the ROTATION MATRIX

$$R_z(45^\circ) = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 & 0 \\ -1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (3)$$

to give

$$\begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = R_z(45^\circ) \begin{bmatrix} x \\ y \\ z \end{bmatrix}, \quad (4)$$

then the simple equation

$$x^2y^2 + x^2z^2 + y^2z^2 + 2kxyz = 0 \quad (5)$$

results. The Roman surface can also be generated using the general method for NONORIENTABLE SURFACES using the polynomial function

$$\mathbf{f}(x, y, z) = (xy, yz, zx) \quad (6)$$

(Pinkall 1986). Setting

$$x = \cos u \sin v \quad (7)$$

$$y = \sin u \sin v \quad (8)$$

$$z = \cos v \quad (9)$$

in the former gives

$$x(u, v) = \frac{1}{2} \sin(2u) \sin^2 v \quad (10)$$

$$y(u, v) = \frac{1}{2} \sin u \cos(2v) \quad (11)$$

$$z(u, v) = \frac{1}{2} \cos u \sin(2v) \quad (12)$$

for  $u \in [0, 2\pi)$  and  $v \in [-\pi/2, \pi/2]$ . Flipping  $\sin v$  and  $\cos v$  and multiplying by 2 gives the form shown by Wang.

A HOMOTOPY (smooth deformation) between the Roman surface and BOY SURFACE is given by the equations

$$x(u, v) = \frac{\sqrt{2} \cos(2u) \cos^2 v + \cos u \sin(2v)}{2 - \alpha \sqrt{2} \sin(3u) \sin(2v)} \quad (13)$$

$$y(u, v) = \frac{\sqrt{2} \sin(2u) \cos^2 v - \sin u \sin(2v)}{2 - \alpha \sqrt{2} \sin(3u) \sin(2v)} \quad (14)$$

$$z(u, v) = \frac{3 \cos^2 v}{2 - \alpha \sqrt{2} \sin(3u) \sin(2v)} \quad (15)$$

for  $u \in [-\pi/2, \pi/2]$  and  $v \in [0, \pi]$  as  $\alpha$  varies from 0 to 1.  $\alpha = 0$  corresponds to the Roman surface and  $\alpha = 1$  to the BOY SURFACE (Wang).

## Rook Number

The rook numbers  $r_n^B$  of an  $n \times n$  BOARD  $B$  are the number of subsets of size  $n$  such that no two elements have the same first or second coordinate. In other word, it is the number of ways of placing  $n$  rooks on  $B$  such that none attack each other. The rook numbers of a board determine the rook numbers of the complementary board  $\bar{B}$ , defined to be  $\mathbf{d} \times \mathbf{d} \setminus B$ . This is known as the ROOK RECIPROCITY THEOREM. The first few rook numbers are 1, 2, 7, 23, 115, 694, 5282, 46066, ... (Sloane's A000903). For an  $n \times n$  board, each  $n \times n$

PERMUTATION MATRIX corresponds to an allowed configuration of rooks.

### Rooks Problem

							R
						R	
					R		
				R			
			R				
		R					
	R						
R							

The rook is a CHESS piece which may move any number of spaces either horizontally or vertically per move. The maximum number of nonattacking rooks which may be placed on an  $n \times n$  CHESSBOARD is  $n$ . This arrangement is achieved by placing the rooks along the diagonal (Madachy 1979). The total number of ways of placing  $n$  nonattacking rooks on an  $n \times n$  board is  $n!$  (Madachy 1979, p. 47). The number of rotationally and reflectively inequivalent ways of placing  $n$  nonattacking rooks on an  $n \times n$  board are 1, 2, 7, 23, 115, 694, ... (Sloane's A000903; Dudeney 1970, p. 96; Madachy 1979, pp. 46–54).

							R
						R	
					R		
				R			
			R				
		R					
	R						
R							

The minimum number of rooks needed to occupy or attack all spaced on an  $8 \times 8$  CHESSBOARD is 8, illustrated above (Madachy 1979).

Consider an  $n \times n$  chessboard with the restriction that, for every subset of  $\{1, \dots, n\}$ , a rook may not be put in column  $s + j \pmod n$  when on row  $j$ , where the rows are numbered  $0, 1, \dots, n - 1$ . Vardi (1991) denotes the number of rook solutions so restricted as  $\text{rook}(s, n)$ .  $\text{rook}(\{1\}, n)$  is simply the number of DERANGEMENTS on  $n$  symbols, known as a SUBFACTORIAL. The first few values are 1, 2, 9, 44, 265, 1854, ... (Sloane's A000166).  $\text{rook}(\{1, 2\}, n)$  is a solution to the MARRIED COUPLES PROBLEM, sometimes known as MÉNAGE NUMBERS. The first few MÉNAGE NUMBERS are  $-1, 1, 0, 2, 13, 80, 579, \dots$  (Sloane's A000179).

Although simple formulas are not known for general  $\{1, \dots, p\}$ , RECURRENCE RELATIONS can be used to compute  $\text{rook}(\{1, \dots, p\}, n)$  in polynomial time for  $p = 3, \dots, 6$  (Metropolis *et al.* 1969, Minc 1978, Vardi 1991).

### Room Square

A Room square (named after T. G. Room) of order  $n$  (for  $n$  ODD) is an arrangement in an  $n \times n$  SQUARE MATRIX of  $n + 1$  objects such that each cell is either empty or holds exactly two different objects. Furthermore, each object appears once in each row and column and each unordered pair occupies exactly one cell. The Room square of order 2 is shown below.

1, 2

### Root

The roots of an equation

$$f(x) = 0 \quad (1)$$

are the values of  $x$  for which the equation is satisfied. The FUNDAMENTAL THEOREM OF ALGEBRA states that every POLYNOMIAL equation of degree  $n$  has exactly  $n$  roots, where some roots may have a multiplicity greater than 1 (in which case they are said to be degenerate).

To find the  $n$ th roots of a COMPLEX NUMBER, solve the equation  $z^n = w$ . Then

$$z^n = |z|^n [\cos(n\theta) + i \sin(n\theta)] = |w| (\cos \phi + i \sin \phi), \quad (2)$$

so

$$|z| = |w|^{1/n} \quad (3)$$

and

$$\arg(z) = \frac{\phi}{n}. \quad (4)$$

Rolle proved that any number has  $n$   $n$ th roots (Boyer 1968, p. 476). Householder (1970) gives an algorithm for constructing root-finding algorithms with an arbitrary order of convergence. Special root-finding techniques can often be applied when the function in question is a POLYNOMIAL.

The sum of the reciprocals of ROOTS of an equation equals the NEGATIVE COEFFICIENT of the linear term in the MACLAURIN SERIES.

see also NEWTON'S RELATIONS

### Root-Mean-Square

The root-mean-square (RMS) of a variate  $x$ , sometimes called the QUADRATIC MEAN, is the SQUARE ROOT of the mean squared value of  $x$ :

$$R(x) \equiv \sqrt{\langle x^2 \rangle} \quad (1)$$

$$= \begin{cases} \sqrt{\frac{\sum_{i=1}^n x_i^2}{n}} & \text{for a discrete distribution} \\ \sqrt{\frac{\int P(x)x^2 dx}{\int P(x) dx}} & \text{for a continuous distribution.} \end{cases} \quad (2)$$

Hoehn and Niven (1985) show that

$$R(a_1 + c, a_2 + c, \dots, a_n + c) < c + R(a_1, a_2, \dots, a_n)$$

for any POSITIVE constant  $c$ .

Physical scientists often use the term root-mean-square as a synonym for STANDARD DEVIATION when they refer to the SQUARE ROOT of the mean squared deviation of a signal from a given baseline or fit.

see also ARITHMETIC-GEOMETRIC MEAN, ARITHMETIC-HARMONIC MEAN, GENERALIZED MEAN, GEOMETRIC MEAN, HARMONIC MEAN, HARMONIC-GEOMETRIC MEAN, MEAN, MEDIAN (STATISTICS), STANDARD DEVIATION, VARIANCE

### Root (Radical)

The  $n$ th root (or "RADICAL") of a quantity  $z$  is a value  $r$  such that  $z = r^n$ , and therefore is the INVERSE FUNCTION to the taking of a POWER. The  $n$ th root is denoted  $r = \sqrt[n]{z}$  or, using POWER notation,  $r = z^{1/n}$ . The special case of the SQUARE ROOT is denoted  $\sqrt{z}$ . The quantities for which a general FUNCTION equals 0 are also called ROOTS, or sometimes ZEROS.

see also CUBE ROOT, ROOT, SQUARE ROOT, VINCULUM

### Root Test

Let  $u_k$  be a SERIES with POSITIVE terms, and let

$$\rho \equiv \lim_{k \rightarrow \infty} u_k^{1/k}.$$

1. If  $\rho < 1$ , the SERIES CONVERGES.
2. If  $\rho > 1$  or  $\rho = \infty$ , the SERIES DIVERGES.
3. If  $\rho = 1$ , the SERIES may CONVERGE or DIVERGE.

This test is also called the CAUCHY ROOT TEST.

see also CONVERGENCE TESTS

### Root (Tree)

A special node which is designated to turn a TREE into a ROOTED TREE. The root is sometimes also called "EVE," and each of the nodes which is one EDGE further away from a given EDGE is called a CHILD. Nodes connected to the same node are then called SIBLINGS.

see also CHILD, ROOTED TREE, SIBLING, TREE

### Root of Unity

The  $n$ th ROOTS of UNITY are ROOTS  $\zeta_k = e^{2\pi i k/p}$  of the CYCLOTOMIC EQUATION

$$x^p = 1,$$

which are known as the DE MOIVRE NUMBERS.

see also CYCLOTOMIC EQUATION, DE MOIVRE'S IDENTITY, DE MOIVRE NUMBER, UNITY

#### References

Courant, R. and Robbins, H. "De Moivre's Formula and the Roots of Unity." §5.3 in *What is Mathematics?: An Elementary Approach to Ideas and Methods*, 2nd ed. Oxford, England: Oxford University Press, pp. 98-100, 1996.

### Rooted Tree

A TREE with a special node called the "ROOT" or "EVE." Denote the number of rooted trees with  $n$  nodes by  $T_n$ , then the GENERATING FUNCTION is

$$T(x) \equiv \sum_{n=0}^{\infty} T_n x^n = x + x^2 + 2x^3 + 4x^4 + 9x^5 + 20x^6 + 48x^7 + 115x^8 + 286x^9 + 719x^{10} + \dots \quad (1)$$

(Sloane's A000081). This POWER SERIES satisfies

$$T(x) = x \exp \left[ \sum_{r=1}^{\infty} \frac{1}{r} T(x^r) \right] \quad (2)$$

$$t(x) = T(x) - \frac{1}{2} [T^2(x) - T(x^2)], \quad (3)$$

where  $t(x)$  is the GENERATING FUNCTION for unrooted TREES. A GENERATING FUNCTION for  $T_n$  can be written using a product involving the sequence itself as

$$x \prod_{n=1}^{\infty} \frac{1}{(1-x^n)^{T_n}} = \sum_{n=1}^{\infty} T_n x^n. \quad (4)$$

The number of rooted trees can also be calculated from the RECURRENCE RELATION

$$T_{i+1} = \frac{1}{i} \sum_{j=1}^i \left( \sum_{d|j} d T_d \right) T_{i-j+1}, \quad (5)$$

with  $T_0 = 0$  and  $T_1 = 1$ , where the second sum is over all  $d$  which DIVIDE  $j$  (Finch).

### Rosatti's Theorem

There is a one-to-one correspondence between the sets of equivalent correspondences (not of value 0) on an irreducible curve of GENUS (CURVE)  $p$ , and the rational COLLINEATIONS of a projective space of  $2p - 1$  dimensions which leave invariant a space of  $p - 1$  dimensions. The number of linearly independent correspondences will be that of linearly independent COLLINEATIONS.

### Rose

A curve which has the shape of a petalled flower. This curve was named RHODONEA by the Italian mathematician Guido Grandi between 1723 and 1728 because it resembles a rose (MacTutor Archive). The polar equation of the rose is

$$r = a \sin(n\theta),$$

or

$$r = a \cos(n\theta).$$

If  $n$  is ODD, the rose is  $n$ -petalled. If  $n$  is EVEN, the rose is  $2n$ -petalled. If  $n$  is IRRATIONAL, then there are an infinite number of petals.

The QUADRIFOLIUM is the rose with  $n = 2$ . The rose is the RADIAL CURVE of the EPICYCLOID.

### Rotation

The turning of an object or coordinate system by an ANGLE about a fixed point. A rotation is an ORIENTATION-PRESERVING ORTHOGONAL TRANSFORMATION. EULER'S ROTATION THEOREM states that an arbitrary rotation can be parameterized using three parameters. These parameters are commonly taken as the EULER ANGLES. Rotations can be implemented using ROTATION MATRICES.

The rotation SYMMETRY OPERATION for rotation by  $360^\circ/n$  is denoted " $n$ ." For periodic arrangements of points ("crystals"), the CRYSTALLOGRAPHY RESTRICTION gives the only allowable rotations as 1, 2, 3, 4, and 6.

### Rotation Formula

A formula which relates the VECTOR  $\mathbf{r}'$  to the ANGLE  $\Phi$  in the above figure (Goldstein 1980). Referring to the figure,

$$\begin{aligned}\mathbf{r}' &= \overrightarrow{ON} + \overrightarrow{NV} + \overrightarrow{VQ} \\ &= \hat{\mathbf{n}}(\hat{\mathbf{n}} \cdot \mathbf{r}) + [\mathbf{r} - \hat{\mathbf{n}}(\hat{\mathbf{n}} \cdot \mathbf{r})] \cos \Phi + (\mathbf{r} \times \hat{\mathbf{n}}) \sin \Phi \\ &= \mathbf{r} \cos \Phi + \hat{\mathbf{n}}(\hat{\mathbf{n}} \cdot \mathbf{r})(1 - \cos \Phi) + (\mathbf{r} \times \hat{\mathbf{n}}) \sin \Phi.\end{aligned}$$

The ANGLE  $\Phi$  and unit normal  $\hat{\mathbf{n}}$  may also be expressed as EULER ANGLES. In terms of the EULER PARAMETERS,

$$\mathbf{r}' = \mathbf{r}(e_0^2 - e_1^2 - e_2^2 - e_3^2) + 2\mathbf{e}(\mathbf{e} \cdot \mathbf{r}) + 2(\mathbf{r} \times \hat{\mathbf{n}}) \sin \Phi.$$

see also EULER ANGLES, EULER PARAMETERS

## Rotation Group

There are three representations of the rotation groups, corresponding to EXPANSION/DILATION, ROTATION, and SHEAR.

## Rotation Matrix

When discussing a ROTATION, there are two possible conventions: rotation of the *axes* and rotation of the *object* relative to fixed axes.

In  $\mathbb{R}^2$ , let a curve be rotated by a clockwise ANGLE  $\theta$ , so that the original axes of the curve are  $\hat{\mathbf{x}}$  and  $\hat{\mathbf{y}}$ , and the new axes of the curve are  $\hat{\mathbf{x}}'$  and  $\hat{\mathbf{y}}'$ . The MATRIX transforming the original curve to the rotated curve, referred to the original  $\hat{\mathbf{x}}$  and  $\hat{\mathbf{y}}$  axes, is

$$R_\theta = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix}, \quad (1)$$

i.e.,

$$\mathbf{x} = R_\theta \mathbf{x}'. \quad (2)$$

On the other hand, let the *axes* with respect to which a curve is measured be rotated by a clockwise ANGLE

$\theta$ , so that the original axes are  $\hat{\mathbf{x}}_0$  and  $\hat{\mathbf{y}}_0$ , and the new axes are  $\hat{\mathbf{x}}$  and  $\hat{\mathbf{y}}$ . Then the MATRIX transforming the coordinates of the curve with respect to  $\hat{\mathbf{x}}$  and  $\hat{\mathbf{y}}$  is given by the MATRIX TRANSPOSE of the above matrix:

$$R'_\theta = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}, \quad (3)$$

i.e.,

$$\mathbf{x} = R'_\theta \mathbf{x}_0. \quad (4)$$

In  $\mathbb{R}^3$ , rotations of the  $x$ -,  $y$ -, and  $z$ -axes give the matrices

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \alpha & \sin \alpha \\ 0 & -\sin \alpha & \cos \alpha \end{bmatrix} \quad (5)$$

$$R_y(\beta) = \begin{bmatrix} \cos \beta & 0 & -\sin \beta \\ 0 & 1 & 0 \\ \sin \beta & 0 & \cos \beta \end{bmatrix} \quad (6)$$

$$R_z(\gamma) = \begin{bmatrix} \cos \gamma & \sin \gamma & 0 \\ -\sin \gamma & \cos \gamma & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (7)$$

see also EULER ANGLES, EULER'S ROTATION THEOREM, ROTATION

## Rotation Number

The period for a QUASIPERIODIC trajectory to pass through the same point in a SURFACE OF SECTION. If the rotation number is IRRATIONAL, the trajectory will densely fill out a curve in the SURFACE OF SECTION. If the rotation number is RATIONAL, it is called the WINDING NUMBER, and only a finite number of points in the SURFACE OF SECTION will be visited by the trajectory. see also QUASIPERIODIC FUNCTION, SURFACE OF SECTION, WINDING NUMBER (MAP)

## Rotation Operator

The rotation operator can be derived from examining an INFINITESIMAL ROTATION

$$\left(\frac{d}{dt}\right)_{\text{space}} = \left(\frac{d}{dt}\right)_{\text{body}} + \boldsymbol{\omega} \times,$$

where  $d/dt$  is the time derivative,  $\boldsymbol{\omega}$  is the ANGULAR VELOCITY, and  $\times$  is the CROSS PRODUCT operator.

see also ACCELERATION, ANGULAR ACCELERATION, INFINITESIMAL ROTATION

## Roth's Removal Rule

If the matrices  $A$ ,  $X$ ,  $B$ , and  $C$  satisfy

$$AX - XB = C,$$

then

$$\begin{bmatrix} I & X \\ 0 & I \end{bmatrix} \begin{bmatrix} A & C \\ 0 & B \end{bmatrix} \begin{bmatrix} I & -X \\ 0 & I \end{bmatrix} = \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix},$$

where  $I$  is the IDENTITY MATRIX.

### Rotoinversion

see IMPROPER ROTATION

### Rotor

A convex figure that can be rotated inside a POLYGON (or POLYHEDRON) while always touching every side (or face). The least AREA rotor in a SQUARE is the REULEAUX TRIANGLE. The least AREA rotor in an EQUILATERAL TRIANGLE is a LENS with two 60° ARCS of CIRCLES and RADIUS equal to the TRIANGLE ALTITUDE.

There exist nonspherical rotors for the TETRAHEDRON, OCTAHEDRON, and CUBE, but not for the DODECAHEDRON and ICOSAHEDRON.

## Round

see NINT

## Rounding

The process of approximating a quantity, usually done for convenience or, in the case of numerical computations, of necessity. If rounding is performed on each of a series of numbers in a long computation, round-off errors can become important, especially if division by a small number ever occurs.

see also SHADOWING THEOREM

### References

- Wilkinson, J. H. *Rounding Errors in Algebraic Processes*. New York: Dover, 1994.

## Routh-Hurwitz Theorem

Consider the CHARACTERISTIC EQUATION

$$|\lambda - A| = \lambda^n + b_1 \lambda^{n-1} + \dots + b_{n-1} \lambda + b_n = 0$$

determining the  $n$  EIGENVALUES  $\lambda$  of a REAL  $n \times n$  MATRIX  $A$ , where  $I$  is the IDENTITY MATRIX. Then the EIGENVALUES  $\lambda$  all have NEGATIVE REAL PARTS if

$$\Delta_1 > 0, \Delta_2 > 0, \dots, \Delta_n > 0,$$

where

$$\Delta_k = \begin{vmatrix} b_1 & 1 & 0 & 0 & 0 & 0 & \dots & 0 \\ b_3 & b_2 & b_1 & 1 & 0 & 0 & \dots & 0 \\ b_5 & b_4 & b_3 & b_2 & b_1 & 0 & \dots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ b_{2k-1} & b_{2k-2} & b_{2k-3} & b_{2k-4} & b_{2k-5} & b_{2k-6} & \dots & b_k \end{vmatrix}.$$

## Routh's Theorem

If the sides of a TRIANGLE are divided in the ratios  $\lambda : 1$ ,  $\mu : 1$ , and  $\nu : 1$ , the CEVIANS form a central TRIANGLE whose AREA is

$$A = \frac{(\lambda\mu\nu - 1)^2}{(\lambda\mu + \lambda + 1)(\mu\nu + \mu + 1)(\nu\lambda + \nu + 1)} \Delta, \quad (1)$$

where  $\Delta$  is the AREA of the original TRIANGLE. For  $\lambda = \mu = \nu \equiv n$ ,

$$A = \frac{(n-1)^2}{n^2 + n + 1} \Delta. \quad (2)$$

For  $n = 2, 3, 4, 5$ , the areas are  $\frac{1}{7}$ ,  $\frac{3}{7}$ , and  $\frac{16}{31}$ . The AREA of the TRIANGLE formed by connecting the division points on each side is

$$A' = \frac{\lambda\mu\nu}{(\lambda+1)(\mu+1)(\nu+1)} \Delta. \quad (3)$$

Routh's theorem gives CEVA'S THEOREM and MENE LAUS' THEOREM as special cases.

see also CEVA'S THEOREM, CEVIAN, MENELAUS' THEOREM

## RSA Encryption

A PUBLIC-KEY CRYPTOGRAPHY ALGORITHM which uses PRIME FACTORIZATION as the TRAPDOOR FUNCTION. Define

$$n \equiv pq \quad (1)$$

for  $p$  and  $q$  PRIMES. Also define a private key  $d$  and a public key  $e$  such that

$$de \equiv 1 \pmod{\phi(n)} \quad (2)$$

$$(e, \phi(n)) = 1, \quad (3)$$

where  $\phi(n)$  is the TOTIENT FUNCTION.

Let the message be converted to a number  $M$ . The sender then makes  $n$  and  $e$  public and sends

$$E = M^e \pmod{n}. \quad (4)$$

To decode, the receiver (who knows  $d$ ) computes

$$E^d \equiv (M^e)^d \equiv M^{ed} \equiv M^{N\phi(n)+1} \equiv M \pmod{n}, \quad (5)$$

since  $N$  is an INTEGER. In order to crack the code,  $d$  must be found. But this requires factorization of  $n$  since

$$\phi(n) = (p-1)(q-1). \quad (6)$$

Both  $p$  and  $q$  should be picked so that  $p \pm 1$  and  $q \pm 1$  are divisible by large PRIMES, since otherwise the POLLARD  $p-1$  FACTORIZATION METHOD or WILLIAMS  $p+1$  FACTORIZATION METHOD potentially factor  $n$  easily. It is also desirable to have  $\phi(\phi(pq))$  large and divisible by large PRIMES.

It is possible to break the cryptosystem by repeated encryption if a unit of  $\mathbb{Z}/\phi(n)\mathbb{Z}$  has small ORDER (Simmons and Norris 1977, Meijer 1996), where  $\mathbb{Z}/s\mathbb{Z}$  is the RING of INTEGERS between 0 and  $s-1$  under addition and multiplication (mod  $s$ ). Meijer (1996) shows that "almost" every encryption exponent  $e$  is safe from breaking using repeated encryption for factors of the form

$$p = 2p_1 + 1 \quad (7)$$

$$q = 2q_1 + 1, \quad (8)$$

where

$$p_1 = 2p_2 + 1 \quad (9)$$

$$q_1 = 2q_2 + 1, \quad (10)$$

and  $p$ ,  $p_1$ ,  $p_2$ ,  $q$ ,  $q_1$ , and  $q_2$  are all PRIMES. In this case,

$$\phi(n) = 4p_1q_1 \quad (11)$$

$$\phi(\phi(n)) = 8p_2q_2. \quad (12)$$

Meijer (1996) also suggests that  $p_2$  and  $q_2$  should be of order  $10^{75}$ .

Using the RSA system, the identity of the sender can be identified as genuine without revealing his private code.

#### RSA Number

Numbers contained in the "factoring challenge" of RSA Data Security, Inc. An additional number which is not part of the actual challenge is the RSA-129 number. The RSA numbers which have been factored are RSA-100, RSA-110, RSA-120, RSA-129, and RSA-130 (Covic *et al.* 1996).

RSA-129 is a 129-digit number used to encrypt one of the first public-key messages. This message was

published by R. Rivest, A. Shamir, and L. Adleman (Gardner 1977), along with the number and a \$100 reward for its decryption. Despite belief that the message encoded by RSA-129 "would take millions of years of break," RSA-129 was factored in 1994 using a distributed computation which harnessed networked computers spread around the globe performing a multiple polynomial QUADRATIC SIEVE FACTORIZATION METHOD. The effort was coordinated by P. Leyland, D. Atkins, and M. Graff. They received 112,011 full factorizations, 1,431,337 single partial factorizations, and 8,881,138 double partial factorizations out of a factor base of 524,339 PRIMES. The final MATRIX obtained was  $188,346 \times 188,346$  square.

The text of the message was "The magic words are squeamish ossifrage" (an ossifrage is a rare, predatory vulture found in the mountains of Europe), and the FACTORIZATION (into a 64-DIGIT number and a 65-DIGIT number) is

**Rubik's Cube**

A  $3 \times 3 \times 3$  CUBE in which the 26 subcubes on the outside are internally hinged in such a way that rotation (by a quarter turn in either direction or a half turn) is possible in any plane of cubes. Each of the six sides is painted a distinct color, and the goal of the puzzle is to return the cube to a state in which each side has a single color after it has been randomized by repeated rotations. The PUZZLE was invented in the 1970s by the Hungarian Erno Rubik and sold millions of copies worldwide over the next decade.

The number of possible positions of Rubik's cube is

$$\frac{8!12!3^8 2^{12}}{2 \cdot 3 \cdot 2} = 43,252,003,274,489,856,000$$

(Turner and Gold 1985). Hoey showed using the PÓLYA-BURNSIDE LEMMA that there are 901,083,404,981,813,616 positions up to conjugacy by whole-cube symmetries.

Algorithms exist for solving a cube from an arbitrary initial position, but they are not necessarily optimal (i.e., requiring a minimum number of turns). The maximum number of turns required for an arbitrary starting position is still not known, although it is bounded from above. Michael Reid (1995) produced the best proven bound of 29 turns (or 42 "quarter-turns"). The proof involves large tables of "subroutines" generated by computer.

However, Dik Winter has produced a program based on work by Kociemba which has solved each of millions of cubes in at most 21 turns. Recently, Richard Korf (1997) has produced a different algorithm which is practical for cubes up to 18 moves away from solved. Out of 10 randomly generated cubes, one was solved in 16 moves, three required 17 moves, and six required 18 moves.

**Rudin-Shapiro Sequence**

The sequence of numbers given by

$$a_n = (-1)^{\sum_{i=1}^{k-1} \epsilon_i \epsilon_{i+1}}, \quad (1)$$

where  $n$  is written in binary

$$n = \epsilon_1 \epsilon_2 \dots \epsilon_k. \quad (2)$$

It is therefore the parity of the number of pairs of consecutive 1s in the BINARY expansion of  $n$ . The SUMMATORY sequence is

$$s_n \equiv \sum_{j=0}^n a_j, \quad (3)$$

which gives

$$s_n = \begin{cases} 2^{k/2} + 1 & \text{if } k \text{ is even} \\ 2^{(k-1)/2} + 1 & \text{if } k \text{ is odd} \end{cases} \quad (4)$$

(Blecksmith and Laud 1995).

### Rule

A usually simple ALGORITHM or IDENTITY. The term is frequently applied to specific orders of NEWTON-COTES FORMULAS.

see also ALGORITHM, BAC-CAB RULE, BODE'S RULE, CHAIN RULE, CRAMER'S RULE, DESCARTES' SIGN RULE, DURAND'S RULE, ESTIMATOR, EULER'S RULE, EULER'S TOTIENT RULE, GOLDEN RULE, HARDY'S RULE, HORNER'S RULE, IDENTITY, L'HOSPITAL'S RULE, LEIBNIZ INTEGRAL RULE, METHOD, OSBORNE'S RULE, PASCAL'S RULE, POWER RULE, PRODUCT RULE, QUARTER SQUARES RULE, QUOTA RULE, QUOTIENT RULE, ROTH'S REMOVAL RULE, RULE OF 72, SIMPSON'S RULE, SLIDE RULE, SUM RULE, TRAPEZOIDAL RULE, WEDDLE'S RULE, ZEUTHEN'S RULE

### Rule of 72

The time required for a given PRINCIPAL to double (assuming  $n = 1$  CONVERSION PERIOD) for COMPOUND INTEREST is given by solving

$$2P = P(1 + r)^t, \quad (1)$$

or

$$t = \frac{\ln 2}{\ln(1 + r)}, \quad (2)$$

where LN is the NATURAL LOGARITHM. This function can be approximated by the so-called "rule of 72":

$$t \approx \frac{0.72}{r}. \quad (3)$$

The above plots show the actual doubling time  $t$  (left plot) and difference between actual and time calculated using the rule of 72 (right plot) as a function of the interest rate  $r$ .

see also COMPOUND INTEREST, INTEREST

### Ruled Surface

A SURFACE which can be swept out by a moving LINE in space and therefore has a parameterization of the form

$$\mathbf{x}(u, v) = \mathbf{b}(u) + v\delta(u), \quad (1)$$

where  $\mathbf{b}$  is called the DIRECTRIX (also called the BASE CURVE) and  $\delta$  is the DIRECTOR CURVE. The straight lines themselves are called RULINGS. The rulings of a ruled surface are ASYMPTOTIC CURVES. Furthermore,

the GAUSSIAN CURVATURE on a ruled REGULAR SURFACE is everywhere NONPOSITIVE.

Examples of ruled surfaces include the elliptic HYPERBOLOID of one sheet (a doubly ruled surface)

$$\begin{bmatrix} a(\cos u \mp v \sin u) \\ b(\sin u \pm \cos u) \\ \pm cv \end{bmatrix} = \begin{bmatrix} a \cos u \\ b \sin u \\ 0 \end{bmatrix} \pm v \begin{bmatrix} -a \cos u \\ b \sin u \\ c \end{bmatrix}, \quad (2)$$

the HYPERBOLIC PARABOLOID (a doubly ruled surface)

$$\begin{bmatrix} a(u + v) \\ \pm bv \\ u^2 + 2uv \end{bmatrix} = \begin{bmatrix} au \\ 0 \\ u^2 \end{bmatrix} + v \begin{bmatrix} a \\ \pm b \\ 2u \end{bmatrix}, \quad (3)$$

PLÜCKER'S CONOID

$$\begin{bmatrix} r \cos \theta \\ r \sin \theta \\ 2 \cos \theta \sin \theta \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 2 \cos \theta \sin \theta \end{bmatrix} + r \begin{bmatrix} \cos \theta \\ \sin \theta \\ 0 \end{bmatrix}, \quad (4)$$

and the MÖBIUS STRIP

$$\begin{bmatrix} a \left[ \cos u + v \cos\left(\frac{1}{2}u\right) \cos u \right] \\ a \left[ \sin u + v \cos\left(\frac{1}{2}u\right) \sin u \right] \\ v \sin\left(\frac{1}{2}u\right) \end{bmatrix} = a \begin{bmatrix} \cos u \\ \sin u \\ 0 \end{bmatrix} + av \begin{bmatrix} \cos\left(\frac{1}{2}u\right) \cos u \\ \cos\left(\frac{1}{2}u\right) \sin u \\ \sin\left(\frac{1}{2}u\right) \end{bmatrix} \quad (5)$$

(Gray 1993).

The only ruled MINIMAL SURFACES are the PLANE and HELICOID (Catalan 1842, do Carmo 1986).

### Ruler

A STRAIGHTEDGE with markings to indicate distances. Although GEOMETRIC CONSTRUCTIONS are sometimes said to be performed with a ruler and COMPASS, the term STRAIGHTEDGE is preferable to ruler since markings are not allowed by the classical Greek rules.

see also COASTLINE PARADOX, COMPASS, GEOMETRIC CONSTRUCTION, GEOMETROGRAPHY, GOLOMB RULER, PERFECT RULER, SIMPLICITY, SLIDE RULE, STRAIGHTEDGE

### Ruler Function

The exponent of the largest POWER of 2 which DIVIDES a given number  $k$ . The values of the ruler function are 1, 2, 1, 3, 1, 2, 1, 4, 1, 2, ... (Sloane's A001511).

### Ruling

One of the straight lines sweeping out a RULED SURFACE. The rulings on a ruled surface are ASYMPTOTIC CURVES.

see also ASYMPTOTIC CURVE, DIRECTOR CURVE, DIRECTRIX (RULED SURFACE), RULED SURFACE

### Run

A run is a sequence of more than one consecutive identical outcomes, also known as a CLUMP. Given  $n$  BERNOULLI TRIALS (say, in the form of COIN TOSSINGS), the probability  $P_t(n)$  of a run of  $t$  consecutive heads or tails is given by the RECURRENCE RELATION

$$P_t(n) = P_t(n-1) + 2^{-t}[1 - P_t(n-t)], \quad (1)$$

where  $P_t(n) = 0$  for  $n < t$  and  $P_t(t) = 2^{1-t}$  (Bloom 1996).

Let  $C_t(m, k)$  denote the number of sequences of  $m$  indistinguishable objects of type  $A$  and  $k$  indistinguishable objects of type  $B$  in which *no*  $t$ -run occurs. The probability that a  $t$ -run *does* occur is then given by

$$P_t(m, k) = 1 - \frac{C_t(m, k)}{\binom{m+k}{k}}, \quad (2)$$

where  $\binom{a}{b}$  is a BINOMIAL COEFFICIENT. Bloom (1996) gives the following recurrence sequence for  $C_t(m, k)$ ,

$$C_t(m, k) = \sum_{i=0}^{t-1} C_t(m-1, k-i) - \sum_{i=1}^{t-1} C_t(m-t, k-i) + e_t(m, k), \quad (3)$$

where

$$e_t(m, k) \equiv \begin{cases} 1 & \text{if } m=0 \text{ and } 0 \leq k < t \\ -1 & \text{if } m=t \text{ and } 0 \leq k < t \\ 0 & \text{otherwise.} \end{cases} \quad (4)$$

Another recurrence which has only a fixed number of terms is given by

$$C_t(m, k) = C_t(m-1, k) + C_t(m, k-1) - C_t(m-t, k-1) - C_t(m-1, k-t) + C_t(m-t, k-t) + e_t^*(m, k), \quad (5)$$

where

$$e_t^*(m, k) \equiv \begin{cases} 1 & \text{if } (m, k) = (0, 0) \text{ or } (t, t) \\ -1 & \text{if } (m, k) = (0, t) \text{ or } (t, 0) \\ 0 & \text{otherwise} \end{cases} \quad (6)$$

(Goulden and Jackson 1983, Bloom 1996). These formulas disprove the assertion of Gardner (1982) that "there will almost always be a clump of six or seven CARDS of the same color" in a normal deck of cards by giving  $P_6(26, 26) = 0.46424$ .

Given  $n$  BERNOULLI TRIALS with a probability of success (heads)  $p$ , the expected number of tails is  $n(1-p)$ , so the expected number of tail runs  $\geq 1$  is  $\approx n(1-p)p$ . Continuing,

$$N_R = n(1-p)p^R \quad (7)$$

is the expected number of runs  $\geq R$ . The longest expected run is therefore given by

$$R = \log_{1/p}[n(1-p)] \quad (8)$$

(Gordon *et al.* 1986, Schilling 1990). Given  $m$  0s and  $n$  1s, the number of possible arrangements with  $u$  runs is

$$f_u = \begin{cases} 2 \binom{m-1}{k-1} \binom{n-1}{k-1} & u \equiv 2k \\ \binom{m-1}{k-1} \binom{n-1}{k-2} + \binom{m-1}{k-2} \binom{n-1}{k-1} & u \equiv 2k+1 \end{cases} \quad (9)$$

for  $k$  an INTEGER, where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. Then

$$P(u \leq u') = \sum_{u=2}^{u'} \frac{f_u}{\binom{m+n}{m}}. \quad (10)$$

Bloom (1996) gives the expected number of noncontiguous  $t$ -runs in a sequence of  $m$  0s and  $n$  1s as

$$E(n, m, t) = \frac{(m+1)(n)_t + (n+1)(m)_t}{(m+n)_t}, \quad (11)$$

where  $(a)_n$  is the POCHHAMMER SYMBOL. For  $m > 10$ ,  $u$  has an approximately NORMAL DISTRIBUTION with MEAN and VARIANCE

$$\mu_u = 1 + \frac{2mn}{m+n} \quad (12)$$

$$\sigma_u^2 = \frac{2mn(2mn - m - n)}{(m+n)^2(m+n-1)}. \quad (13)$$

see also COIN TOSSING, EULERIAN NUMBER, PERMUTATION,  $s$ -RUN

### Runge-Kutta Method

A method of integrating ORDINARY DIFFERENTIAL EQUATIONS by using a trial step at the midpoint of an interval to cancel out lower-order error terms. The second-order formula is

$$\begin{aligned}k_1 &= hf(x_n, y_n) \\k_2 &= hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_1) \\y_{n+1} &= y_n + k_2 + \mathcal{O}(h^3),\end{aligned}$$

and the fourth-order formula is

$$\begin{aligned}k_1 &= hf(x_n, y_n) \\k_2 &= hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_1) \\k_3 &= hf(x_n + \tfrac{1}{2}h, y_n + \tfrac{1}{2}k_2) \\k_4 &= hf(x_n + h, y_n + k_3) \\y_{n+1} &= y_n + \tfrac{1}{6}k_1 + \tfrac{1}{3}k_2 + \tfrac{1}{3}k_3 + \tfrac{1}{6}k_4 + \mathcal{O}(h^5).\end{aligned}$$

(Press *et al.* 1992). This method is reasonably simple and robust and is a good general candidate for numerical solution of differential equations when combined with an intelligent adaptive step-size routine.

### Running Knot

A KNOT which tightens around an object when strained but slackens when the strain is removed. Running knots are sometimes also known as slip knots or nooses.

### References

- Owen, P. *Knots*. Philadelphia, PA: Courage, p. 60, 1993.

### Russell's Antinomy

Let  $R$  be the set of all sets which are not members of themselves. Then  $R$  is neither a member of itself nor not a member of itself. Symbolically, let  $R = \{x : x \notin x\}$ . Then  $R \in R$  IFF  $R \notin R$ .

Bertrand Russell discovered this PARADOX and sent it in a letter to G. Frege just as Frege was completing *Grundlagen der Arithmetik*. This invalidated much of the rigor of the work, and Frege was forced to add a note at the end stating, "A scientist can hardly meet with anything more undesirable than to have the foundation give way just as the work is finished. I was put in this position by a letter from Mr. Bertrand Russell when the work was nearly through the press."

### Russell's Paradox

see RUSSELL'S ANTINOMY

**Russian Multiplication**

Also called ETHIOPIAN MULTIPLICATION. To multiply two numbers  $a$  and  $b$ , write  $a_0 \equiv a$  and  $b_0 \equiv b$  in two columns. Under  $a_0$ , write  $\lfloor a_0/2 \rfloor$ , where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, and under  $b_0$ , write  $2b_0$ . Continue until  $a_i = 1$ . Then cross out any entries in the  $b$  column which are opposite an EVEN NUMBER in the  $a$  column and add the  $b$  column. The result is the desired product. For example, for  $a = 27, b = 35$

27	35
13	70
6	<del>140</del>
3	280
1	<del>560</del>
	945

**Russian Roulette**

Russian roulette is a GAME of chance in which one or more of the six chambers of a gun are filled with bullets, the magazine is rotated at random, and the gun is shot. The shooter bets on whether the chamber which rotates into place will be loaded. If it is, he loses not only his bet but his life.

A modified version is considered by Blom *et al.* (1996) and Blom (1989). In this variant, the revolver is loaded with a single bullet, and two duelists alternately spin the chamber and fire at themselves until one is killed. The probability that the first duelist is killed is then  $6/11$ .

**Ryser Formula**

A formula for the PERMANENT of a MATRIX

$$\text{perm}(a_{ij}) = (-1)^n \sum_{s \subseteq \{1, \dots, n\}} (-1)^{|s|} \prod_{i=1}^n \sum_{j \in s} a_{ij},$$

where the SUM is over all SUBSETS of  $\{1, \dots, n\}$ , and  $|s|$  is the number of elements in  $s$ . The formula can be optimized by picking the SUBSETS so that only a single element is changed at a time (which is precisely a GRAY CODE), reducing the number of additions from  $n^2$  to  $n$ .

It turns out that the number of disks moved after the  $k$ th step in the TOWERS OF HANOI is the same as the element which needs to be added or deleted in the  $k$ th ADDEND of the RYSER FORMULA (Gardner 1988, Vardi 1991, p. 111)

# S

## *s*-Additive Sequence

A generalization of an ULAM SEQUENCE in which each term is the SUM of two earlier terms in exactly *s* ways. (*s*, *t*)-additive sequences are a further generalization in which each term has exactly *s* representations as the SUM of *t* distinct earlier numbers. It is conjectured that 0-additive sequences ultimately have periodic differences of consecutive terms (Guy 1994, p. 233).

## *s*-Cluster

*N.B.* A detailed on-line essay by S. Finch was the starting point for this entry.

Let an  $n \times n$  MATRIX have entries which are either 1 (with probability *p*) or 0 (with probability  $q = 1 - p$ ). An *s*-cluster is an isolated group of *s* adjacent (i.e., horizontally or vertically connected) 1s. Let  $C_n$  be the total number of "SITE" clusters. Then the value

$$K_S(p) = \lim_{n \rightarrow \infty} \frac{\langle C_n \rangle}{n^2}, \quad (1)$$

called the MEAN CLUSTER COUNT PER SITE or MEAN CLUSTER DENSITY, exists. Numerically, it is found that  $K_S(1/2) \approx 0.065770 \dots$  (Ziff *et al.* 1997).

Considering instead "BOND" clusters (where numbers are assigned to the edges of a grid) and letting  $C_n$  be the total number of bond clusters, then

$$K_B(p) \equiv \lim_{n \rightarrow \infty} \frac{\langle C_n \rangle}{n^2} \quad (2)$$

exists. The analytic value is known for  $p = 1/2$ ,

$$K_B\left(\frac{1}{2}\right) = \frac{3}{2}\sqrt{3} - \frac{41}{16} \quad (3)$$

(Ziff *et al.* 1997).

## *s*-Run

*N.B.* A detailed on-line essay by S. Finch was the starting point for this entry.

Let **v** be a *n*-VECTOR whose entries are each 1 (with probability *p*) or 0 (with probability  $q = 1 - p$ ). An *s*-run is an isolated group of *s* consecutive 1s. Ignoring the boundaries, the total number of runs  $R_n$  satisfies

$$K_n = \frac{\langle R_n \rangle}{n} = (1 - p)^2 \sum_{s=1}^n p^s = p(1 - p)(1 - p^n),$$

so

$$K(p) \equiv \lim_{n \rightarrow \infty} K_n = p(1 - p),$$

which is called the MEAN RUN COUNT PER SITE or MEAN RUN DENSITY in PERCOLATION THEORY.

## Saalschützian

For a GENERALIZED HYPERGEOMETRIC FUNCTION

$${}_{p+1}F_p \left[ \begin{matrix} \alpha_1, \alpha_2, \dots, \alpha_{p+1} \\ \beta_1, \beta_2, \dots, \beta_p \end{matrix} ; z \right],$$

the Saalschützian *S* is defined if

$$\sum \beta = \sum \alpha + 1.$$

see also GENERALIZED HYPERGEOMETRIC FUNCTION

## Saalschütz's Theorem

$${}_3F_2 \left[ \begin{matrix} -x, -y, -z \\ n+1, -x-y-z \end{matrix} \right] = \frac{\Gamma(n+1)\Gamma(x+y+n+1)}{\Gamma(x+n+1)\Gamma(y+n+1)} \times \frac{\Gamma(y+z+n+1)\Gamma(z+x+n+1)}{\Gamma(z+n+1)\Gamma(x+y+z+n+1)},$$

where  ${}_3F_2(a, b, c; d, e; z)$  is a GENERALIZED HYPERGEOMETRIC FUNCTION and  $\Gamma(z)$  is the GAMMA FUNCTION.

It can be derived from the DOUGALL-RAMANUJAN IDENTITY and written in the symmetric form

$${}_3F_2(a, b, c; d, e; 1) = \frac{(d-a)_{|c|}(d-b)_{|c|}}{d_{|c|}(d-a-b)_{|c|}}$$

for  $d+e = a+b+c+1$  with  $c$  a negative integer and  $(a)_n$  the POCHHAMMER SYMBOL (Petkovšek *et al.* 1996).

see also DOUGALL-RAMANUJAN IDENTITY, GENERALIZED HYPERGEOMETRIC FUNCTION

### Saddle

A SURFACE possessing a SADDLE POINT.

see also HYPERBOLIC PARABOLOID, MONKEY SADDLE, SADDLE POINT (FUNCTION)

### Saddle-Node Bifurcation

see FOLD BIFURCATION

### Saddle Point (Fixed Point)

see HYPERBOLIC FIXED POINT (DIFFERENTIAL EQUATIONS), HYPERBOLIC FIXED POINT (MAP)

### Saddle Point (Function)

A POINT of a FUNCTION or SURFACE which is a STATIONARY POINT but not an EXTREMUM. An example of a 1-D FUNCTION with a saddle point is  $f(x) = x^3$ , which has

$$\begin{aligned} f'(x) &= 3x^2 \\ f''(x) &= 6x \\ f'''(x) &= 6. \end{aligned}$$

This function has a saddle point at  $x_0 = 0$  by the EXTREMUM TEST since  $f''(x_0) = 0$  and  $f'''(x_0) = 6 \neq 0$ . An example of a SURFACE with a saddle point is the MONKEY SADDLE.

### Saddle Point (Game)

For a general two-player ZERO-SUM GAME,

$$\min_{i \leq m} \min_{j \leq n} a_{ij} \leq \min_{j \leq n} \max_{i \leq m} a_{ij}.$$

If the two are equal, then write

$$\min_{i \leq m} \min_{j \leq n} a_{ij} = \min_{j \leq n} \max_{i \leq m} a_{ij} \equiv v,$$

where  $v$  is called the VALUE of the GAME. In this case, there exist optimal strategies for the first and second players.

A NECESSARY and SUFFICIENT condition for a saddle point to exist is the presence of a PAYOFF MATRIX element which is both a minimum of its row and a maximum of its column. A GAME may have more than one saddle point, but all must have the same VALUE.

#### Saint Anthony's Cross

A CROSS also called the tau cross or crux commissa.

see also CROSS

#### Saint Petersburg Paradox

Consider a game in which a player bets on whether a given Toss of a COIN will turn up heads or tails. If he bets \$1 that heads will turn up on the first throw, \$2 that heads will turn up on the second throw (if it did not turn up on the first), \$4 that heads will turn up on the third throw, etc., his expected *payoff* is

$$\frac{1}{2}(1) + \frac{1}{4}(2) + \frac{1}{8}(4) + \dots = \frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \dots = \infty.$$

Apparently, the first player can be in the hole by any amount of money and still come out ahead in the end. This PARADOX was first proposed by Daniel Bernoulli.

The paradox arises as a result of muddling the distinction between the amount of the final payoff and the net amount won in the game. It is misleading to consider the payoff without taking into account the amount lost on previous bets, as can be shown as follows. At the time the player first wins (say, on the  $n$ th toss), he will have lost

$$\sum_{k=1}^{n-1} 2^{k-1} = 2^{n-1} - 1$$

dollars. In this toss, however, he wins  $2^{n-1}$  dollars. This means that the net gain for the player is a whopping \$1, no matter how many tosses it takes to finally win. As expected, the large payoff after a long run of tails is exactly balanced by the large amount that the player has to invest.

In fact, by noting that the probability of winning on the  $n$ th toss is  $1/2^n$ , it can be seen that the probability distribution for the number of tosses needed to win is simply a GEOMETRIC DISTRIBUTION with  $p = 1/2$ .

#### Salem Constants

Each point of the PISOT-VIJAYARAGHAVAN CONSTANTS  $S$  is a LIMIT POINT from both sides of a set  $T$  known as the Salem constants (Salem 1945). The Salem constants are algebraic INTEGERS  $> 1$  in which one or more of the conjugates is on the UNIT CIRCLE with the others inside (Le Lionnais 1983, p. 150). The smallest known Salem number was found by Lehmer (1933) as the largest REAL ROOT of

$$x^{10} + x^9 - x^7 - x^6 - x^5 - x^4 - x^3 + x + 1 = 0,$$

which is

$$\sigma_1 = 1.176280818\dots$$

(Le Lionnais 1983, p. 35). Boyd (1977) found the following table of small Salem numbers, and suggested that  $\sigma_1$ ,  $\sigma_2$ ,  $\sigma_3$ , and  $\sigma_4$  are the smallest Salem numbers. The NOTATION 1 1 0 -1 -1 -1 is short for 1 1 0 -1 -1 -1 -1 -1 0 1 1, the coefficients of the above polynomial.

#### Salesman Problem

see TRAVELING SALESMAN PROBLEM

#### Salient Point

A point at which two noncrossing branches of a curve meet with different tangents.

see also CUSP

#### Salinon

The above figure formed from four connected SEMICIRCLES. The word salinon is Greek for salt cellar, which the figure resembles.

see also ARBELOS, PIECEWISE CIRCULAR CURVE, SEMICIRCLE

#### Salmon's Theorem

Given a track bounded by two confocal ELLIPSES, if a ball is rolled so that its trajectory is tangent to the inner ELLIPSE, the ball's trajectory will be tangent to the inner ELLIPSE following all subsequent caroms as well.

#### References

- Salmon, G. *A Treatise on Conic Sections*. New York: Chelsea, p. 182, 1954.

#### Saltus

The word saltus has two different meanings: either a jump or an oscillation of a function.

#### Sample Proportion

Let there be  $x$  successes out of  $n$  BERNOULLI TRIALS. The sample proportion is the fraction of samples which were successes, so

$$\hat{p} = \frac{x}{n}. \quad (1)$$

For large  $n$ ,  $\hat{p}$  has an approximately NORMAL DISTRIBUTION. Let RE be the RELATIVE ERROR and SE the STANDARD ERROR, then

$$\langle p \rangle = p \quad (2)$$

$$SE(\hat{p}) \equiv \sigma(\hat{p}) = \sqrt{\frac{p(1-p)}{n}} \quad (3)$$

$$RE(\hat{p}) = \sqrt{\frac{2\hat{p}(1-\hat{p})}{n}} \operatorname{erf}^{-1}(CI), \quad (4)$$

where CI is the CONFIDENCE INTERVAL and  $\operatorname{erf} x$  is the ERF function. The number of tries needed to determine  $p$  with RELATIVE ERROR RE and CONFIDENCE INTERVAL CI is

$$n = \frac{2[\operatorname{erf}^{-1}(CI)]^2 \hat{p}(1-\hat{p})}{(RE)^2}. \quad (5)$$

### Sample Space

Informally, the sample space for a given set of events is the set of all possible values the events may assume. Formally, the set of possible events for a given variate forms a SIGMA ALGEBRA, and sample space is defined as the largest set in the SIGMA ALGEBRA.

see also PROBABILITY SPACE, RANDOM VARIABLE, SIGMA ALGEBRA, STATE SPACE

### Sample Variance

To estimate the population VARIANCE from a sample of  $N$  elements with a priori *unknown* MEAN (i.e., the MEAN is estimated from the sample itself), we need an unbiased ESTIMATOR for  $\sigma$ . This is the  $k$ -STATISTIC  $k_2$ , where

$$k_2 = \frac{N}{N-1} m_2 \quad (1)$$

and  $m_2 \equiv s^2$  is the sample variance

$$s^2 \equiv \frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^2. \quad (2)$$

Note that some authors prefer the definition

$$s'^2 \equiv \frac{1}{N-1} \sum_{i=1}^N (x_i - \bar{x})^2, \quad (3)$$

since this makes the sample variance an UNBIASED ESTIMATOR for the population variance.

see also  $k$ -STATISTIC, VARIANCE

### Sampling

For infinite precision sampling of a band-limited signal at the NYQUIST FREQUENCY, the signal-to-noise ratio after  $N_q$  samples is

$$\text{SNR} = \frac{\langle r_\infty \rangle}{\sigma_\infty} = \frac{\rho \sigma^2}{\sigma^2 N_q^{-1/2} \sqrt{1 + \rho^2}} = \frac{\rho}{\sqrt{1 + \rho^2}} \sqrt{N_q}, \quad (1)$$

where  $\rho$  is the normalized cross-correlation COEFFICIENT

$$\rho \equiv \frac{\langle x(t) \rangle \langle y(t) \rangle}{\sqrt{\langle x^2(t) \rangle \langle y^2(t) \rangle}}. \quad (2)$$

For  $\rho \ll 1$ ,

$$\text{SNR} \approx \rho \sqrt{N_q}. \quad (3)$$

The identical result is obtained for oversampling. For undersampling, the SNR decreases (Thompson *et al.* 1986).

Thompson, A. R.; Moran, J. M.; and Swenson, G. W. Jr. *Interferometry and Synthesis in Radio Astronomy*. New York: Wiley, pp. 214–216, 1986.

### Sampling Function

The 1-D sampling function is given by

$$S(x) = \sum_{n=-\infty}^{\infty} \delta(x - n\Delta x),$$

where  $\delta$  is the DIRAC DELTA FUNCTION. The 2-D version is

$$S(u, v) = \sum \delta(u - u_n, v - v_n),$$

which can be weighted to

$$S(u, v) = \sum R_n T_n D_n \delta(u - u_n, v - v_n),$$

where  $R_n$  is a reliability weight,  $D_n$  is a density weight (WEIGHTING FUNCTION), and  $T_n$  is a taper.

see also SHAH FUNCTION, SINC FUNCTION

### Sampling Theorem

In order for a band-limited (i.e., one with a zero POWER SPECTRUM for frequencies  $f > B$ ) baseband ( $f > 0$ ) signal to be reconstructed fully, it must be sampled at a rate  $f \geq 2B$ . A signal sampled at  $f = 2B$  is said to be NYQUIST SAMPLED, and  $f = 2B$  is called the NYQUIST FREQUENCY. No information is lost if a signal is sampled at the NYQUIST FREQUENCY, and no additional information is gained by sampling faster than this rate.

see also ALIASING, NYQUIST FREQUENCY, NYQUIST SAMPLING, OVERSAMPLING

### San Marco Fractal

The FRACTAL  $J(-3/4, 0)$ , where  $J$  is the JULIA SET. It slightly resembles the MANDELBROT SET.

**Šarkovskii's Theorem**

Order the NATURAL NUMBERS as follows:

$$\begin{aligned} 3 < 5 < 7 < 9 < 11 < 13 < 15 < \dots < 2 \cdot 3 < 2 \cdot 5 < 2 \cdot 7 \\ < 2 \cdot 9 < \dots < 2 \cdot 2 \cdot 3 < 2 \cdot 2 \cdot 5 < 2 \cdot 2 \cdot 7 \\ < 2 \cdot 2 \cdot 9 < \dots < 2 \cdot 2 \cdot 2 \cdot 3 < \dots \\ < 2^5 < 2^4 < 2^3 < 2^2 < 2 < 1. \end{aligned}$$

Now let  $F$  be a CONTINUOUS FUNCTION from the REALS to the REALS and suppose  $p < q$  in the above ordering. Then if  $F$  has a point of LEAST PERIOD  $p$ , then  $F$  also has a point of LEAST PERIOD  $q$ .

A special case of this general result, also known as Šarkovskii's theorem, states that if a CONTINUOUS REAL function has a PERIODIC POINT with period 3, then there is a PERIODIC POINT of period  $n$  for every INTEGER  $n$ .

A converse to Šarkovskii's theorem says that if  $p < q$  in the above ordering, then we can find a CONTINUOUS FUNCTION which has a point of LEAST PERIOD  $q$ , but does not have any points of LEAST PERIOD  $p$  (Elaydi 1996). For example, there is a CONTINUOUS FUNCTION with no points of LEAST PERIOD 3 but having points of all other LEAST PERIODS.

**Sárközy's Theorem**

A partial solution to the ERDŐS SQUAREFREE CONJECTURE which states that the BINOMIAL COEFFICIENT  $\binom{2n}{n}$  is never SQUAREFREE for all sufficiently large  $n \geq n_0$ . Sárközy (1985) showed that if  $s(n)$  is the square part of the BINOMIAL COEFFICIENT  $\binom{2n}{n}$ , then

$$\ln s(n) \sim (\sqrt{2} - 2)\zeta\left(\frac{1}{2}\right)\sqrt{n},$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION. An upper bound on  $n_0$  of  $2^{8,000}$  has been obtained.

**Sarrus Linkage**

A LINKAGE which converts circular to linear motion using a hinged square.

see also HART'S INVERSOR, LINKAGE, PEAUCELLIER INVERSOR

**Sarrus Number**

see POULET NUMBER

**SAS Theorem**

Specifying two sides and the ANGLE between them uniquely determines a TRIANGLE. Let  $b$  be the base length and  $h$  be the height. Then the AREA is

$$K = \frac{1}{2}ch = \frac{1}{2}ac \sin B. \quad (1)$$

The length of the third side is given by the LAW OF COSINES,

$$b^2 = a^2 + c^2 - 2ac \cos B,$$

so

$$b = \sqrt{a^2 + c^2 - 2ac \cos B}. \quad (2)$$

Using the LAW OF SINES

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C} \quad (3)$$

then gives the two other ANGLES as

$$A = \sin^{-1} \left( \frac{a \sin B}{\sqrt{a^2 + c^2 - 2ac \cos B}} \right) \quad (4)$$

$$C = \sin^{-1} \left( \frac{c \sin B}{\sqrt{a^2 + c^2 - 2ac \cos B}} \right) \quad (5)$$

## Satellite Knot

Let  $K_1$  be a knot inside a TORUS. Now knot the TORUS in the shape of a second knot (called the COMPANION KNOT)  $K_2$ . Then the new knot resulting from  $K_1$  is called the satellite knot  $K_3$ . COMPOSITE KNOTS are special cases of satellite knots. The only KNOTS which are not HYPERBOLIC KNOTS are TORUS KNOTS and satellite knots (including COMPOSITE KNOTS). No satellite knot is an ALMOST ALTERNATING KNOT.

## Scalar Curvature

see CURVATURE SCALAR

## Scalar Field

A MAP  $f : \mathbb{R}^n \rightarrow \mathbb{R}$  which assigns each  $\mathbf{x}$  a SCALAR FUNCTION  $f(\mathbf{x})$ .

see also VECTOR FIELD

### References

Morse, P. M. and Feshbach, H. “Scalar Fields.” §1.1 in *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 4–8, 1953.

## Scalar Function

A function  $f(x_1, \dots, x_n)$  of one or more variables whose RANGE is one-dimensional, as compared to a VECTOR FUNCTION, whose RANGE is three-dimensional (or, in general,  $n$ -dimensional).

see also COMPLEX FUNCTION, REAL FUNCTION, VECTOR FUNCTION

## Scalar Potential

A conservative VECTOR FIELD (for which the CURL  $\nabla \times \mathbf{F} = \mathbf{0}$ ) may be assigned a scalar potential

$$\begin{aligned} \phi(x, y, z) - \phi(0, 0, 0) &\equiv - \int_C \mathbf{F} \cdot d\mathbf{s} \\ &= - \int_{(0,0,0)}^{(x,y,0)} F_1(t, 0, 0) dt + \int_{(x,0,0)}^{(x,y,0)} F_2(x, t, 0) dt \\ &\quad + \int_{(x,y,0)}^{x,y,z} F_3(x, y, t) dt, \end{aligned}$$

where  $\int_C \mathbf{F} \cdot d\mathbf{s}$  is a LINE INTEGRAL.

see also POTENTIAL FUNCTION, VECTOR POTENTIAL

## Scalar Triple Product

The VECTOR product

$$\begin{aligned} [\mathbf{A}, \mathbf{B}, \mathbf{C}] &\equiv \mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \mathbf{B} \cdot (\mathbf{C} \times \mathbf{A}) \\ &= \mathbf{C} \cdot (\mathbf{A} \times \mathbf{B}) = \begin{vmatrix} A_1 & A_2 & A_3 \\ B_1 & B_2 & B_3 \\ C_1 & C_2 & C_3 \end{vmatrix}, \end{aligned}$$

which yields a SCALAR (actually, a PSEUDOSCALAR).

The VOLUME of a PARALLELEPIPED whose sides are given by the vectors **A**, **B**, and **C** is

$$V_{\text{parallelepiped}} = |\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C})|.$$

### Scale

see BASE (NUMBER)

### Scale Factor

For a diagonal METRIC TENSOR  $g_{ij} = g_{ii}\delta_{ij}$ , where  $\delta_{ij}$  is the KRONECKER DELTA, the scale factor is defined by

$$h_i \equiv \sqrt{g_{ii}}. \quad (1)$$

The LINE ELEMENT (first FUNDAMENTAL FORM) is then given by

$$ds^2 = g_{11} dx_{11}^2 + g_{22} dx_{22}^2 + g_{33} dx_{33}^2 \quad (2)$$

$$= h_1^2 dx_{11}^2 + h_2^2 dx_{22}^2 + h_3^2 dx_{33}^2. \quad (3)$$

The scale factor appears in vector derivatives of coordinates in CURVILINEAR COORDINATES.

see also CURVILINEAR COORDINATES, FUNDAMENTAL FORMS, LINE ELEMENT

### Scalene Triangle

A TRIANGLE with three unequal sides.

### Schanuel's Conjecture

Let  $\lambda_1, \dots, \lambda_n \in \mathbb{C}$  be linearly independent over the RATIONALS  $\mathbb{Q}$ , then

$$\mathbb{Q}(\lambda_1, \dots, \lambda_n, e^{\lambda_1}, \dots, e^{\lambda_n})$$

has TRANSCENDENCE degree at least  $n$  over  $\mathbb{Q}$ . Schanuel's conjecture is a generalization of the LINDEMANN-WEIERSTRASS THEOREM. If the conjecture is true, then it follows that  $e$  and  $\pi$  are algebraically independent. McIntyre (1991) proved that the truth of Schanuel's conjecture also guarantees that there are no unexpected exponential-algebraic relations on the INTEGERS  $\mathbb{Z}$  (Marker 1996).

**Scherk's Minimal Surfaces**

A class of MINIMAL SURFACES discovered by Scherk (1834) which were the first new surfaces discovered since Meusnier in 1776. Scherk's first surface is doubly periodic. Scherk's second surface, illustrated above, can be written parametrically as

$$\begin{aligned}x &= 2\Re[\ln(1 + re^{i\theta}) - \ln(1 - re^{i\theta})] \\y &= \Re[4i \tan^{-1}(re^{i\theta})] \\z &= \Re\{2i(-\ln[1 - r^2 e^{2i\theta}] + \ln[1 + r^2 e^{2i\theta}])\}\end{aligned}$$

for  $\theta \in [0, 2\pi)$ , and  $r \in (0, 1)$ . Scherk's first surface has been observed to form in layers of block copolymers (Peterson 1988).

von Seggern (1993) calls

$$z = c \ln \left[ \frac{\cos(2\pi y)}{\cos(2\pi x)} \right]$$

"Scherk's surface." Beautiful images of wood sculptures of Scherk surfaces are illustrated by Séquin.

**Schinzel Circle**

A CIRCLE having a given number of LATTICE POINTS on its CIRCUMFERENCE. The Schinzel circle halving  $n$  lattice points is given by the equation

$$\begin{cases} (x - \frac{1}{2})^2 + y^2 = \frac{1}{4} 5^{k-1} & \text{for } n = 2k \text{ even} \\ (x - \frac{1}{3})^2 + y^2 = \frac{1}{9} 5^{2k} & \text{for } n = 2k + 1 \text{ odd.} \end{cases}$$

Note that these solutions do not necessarily have the smallest possible RADIUS. For example, while the Schinzel circle centered at  $(1/3, 0)$  and with radius  $625/3$

has nine lattice points on its circumference, so does the circle centered at  $(1/3, 0)$  with radius  $65/3$ .

### Schinzel's Hypothesis

If  $f_1(x), \dots, f_s(x)$  are irreducible POLYNOMIALS with INTEGER COEFFICIENTS such that no INTEGER  $n > 1$  divides  $f_1(x), \dots, f_s(x)$  for all INTEGERS  $x$ , then there should exist infinitely many  $x$  such that  $f_1(x), \dots, f_s(x)$  are simultaneous PRIME.

#### References

### Schinzel's Theorem

For every POSITIVE INTEGER  $n$ , there exists a CIRCLE in the plane having exactly  $n$  LATTICE POINTS on its CIRCUMFERENCE. The theorem is based on the number  $r(n)$  of integral solutions  $(x, y)$  to the equation

$$x^2 + y^2 = n, \quad (1)$$

given by

$$r(n) = 4(d_1 - d_3), \quad (2)$$

where  $d_1$  is the number of divisors of  $n$  of the form  $4k+1$  and  $d_3$  is the number of divisors of the form  $4k+3$ . It explicitly identifies such circles (the SCHINZEL CIRCLES) as

$$\begin{cases} (x - \frac{1}{2})^2 + y^2 = \frac{1}{4}5^{k-1} & \text{for } n = 2k \\ (x - \frac{1}{3})^2 + y^2 = \frac{1}{9}5^{2k} & \text{for } n = 2k + 1. \end{cases} \quad (3)$$

Note, however, that these solutions do not necessarily have the smallest possible radius.

**Schlömilch's Function**

$$\begin{aligned} S(\nu, z) &\equiv \int_0^\infty (1+t)^{-\nu} e^{-zt} dt = z^{\nu-1} e^z \int_z^\infty u^{-\nu} e^{-u} du \\ &= z^{\nu/2-1} e^{z/2} W_{-\nu/2, (1-\nu)/2}(z), \end{aligned}$$

where  $W_{k,m}(z)$  is the WHITTAKER FUNCTION.

**Schlömilch's Series**

A FOURIER SERIES-like expansion of a twice continuously differentiable function

$$f(x) = \frac{1}{2}a_0 + \sum_{n=1}^{\infty} a_n J_0(nx)$$

for  $0 < x < \pi$ , where  $J_0(x)$  is a zeroth order BESSEL FUNCTION OF THE FIRST KIND and

$$\begin{aligned} a_0 &\equiv 2f(0) + \frac{2}{\pi} \int_0^\pi du \int_0^{\pi/2} f'(u \sin \phi) d\phi \\ a_n &\equiv \frac{2}{\pi} \int_0^\pi du \int_0^{\pi/2} u f'(u \sin \phi) \cos(n\pi) d\phi. \end{aligned}$$

A special case gives the amazing identity

$$1 = J_0(z) + 2 \sum_{n=1}^{\infty} J_{2n}(z) = [J_0(z)]^2 + 2 \sum_{n=1}^{\infty} [J_n(z)]^2.$$

**Schönflies Theorem**

If  $J$  is a simple closed curve in  $\mathbb{R}^2$ , the closure of one of the components of  $\mathbb{R}^2 - J$  is HOMEOMORPHIC with the unit 2-BALL. This theorem may be proved using the RIEMANN MAPPING THEOREM, but the easiest proof is via MORSE THEORY.

The generalization to  $n$ -D is called MAZUR'S THEOREM. It follows from the Schönflies theorem that any two KNOTS of  $\mathbb{S}^1$  in  $\mathbb{S}^2$  or  $\mathbb{R}^2$  are equivalent.

**Schröder-Bernstein Theorem**

The Schröder-Bernstein theorem for numbers states that if

$$n \leq m \leq n,$$

then  $m = n$ . For SETS, the theorem states that if there are INJECTIONS of the SET  $A$  into the SET  $B$  and of  $B$  into  $A$ , then there is a BIJECTIVE correspondence between  $A$  and  $B$  (i.e., they are EQUIPOLLENT).

see also BIJECTION, EQUIPOLLENT, INJECTION

**Schröder's Equation**

$$f(\lambda z) = R(z),$$

where  $R(z) = \lambda x + a_2 x^2 + \dots$ ,  $\lambda \equiv R'(0)$ ,  $|\lambda| = 1$ , and  $\lambda^n \neq 1$  for all  $n \in \mathbb{N}$ .

**Schröder's Method**

Two families of equations used to find roots of nonlinear functions of a single variable. The "B" family is more robust and can be used in the neighborhood of degenerate multiple roots while still providing a guaranteed convergence rate. Almost all other root-finding methods can be considered as special cases of Schröder's method. Householder humorously claimed that papers on root-finding could be evaluated quickly by looking for a citation of Schröder's paper; if the reference were missing, the paper probably consisted of a rediscovery of a result due to Schröder (Stewart 1993).

One version of the "A" method is obtained by applying NEWTON'S METHOD to  $f/f'$ ,

$$x_{n+1} = x_n - \frac{f(x_n)f'(x_n)}{[f'(x_n)]^2 - f(x_n)f''(x_n)}$$

(Scavo and Thoo 1995).

**Schröder Number**

The Schröder number  $S_n$  is the number of LATTICE PATHS in the Cartesian plane that start at  $(0, 0)$ , end at  $(n, n)$ , contain no points above the line  $y = x$ , and are composed only of steps  $(0, 1)$ ,  $(1, 0)$ , and  $(1, 1)$ , i.e.,  $\rightarrow$ ,  $\uparrow$ , and  $\nearrow$ . The diagrams illustrating the paths generating  $S_1$ ,  $S_2$ , and  $S_3$  are illustrated above. The numbers  $S_n$  are given by the RECURRENCE RELATION

$$S_n = S_{n-1} + \sum_{k=0}^{n-1} S_k S_{n-1-k},$$

where  $S_0 = 1$ , and the first few are 2, 6, 22, 90, ... (Sloane's A006318). The Schröder Numbers bear the same relation to the DELANNOY NUMBERS as the CATALAN NUMBERS do to the BINOMIAL COEFFICIENTS.

**Schur's Lemma**

For each  $k \in \mathbb{N}$  there exists a largest INTEGER  $s(k)$  (known as the SCHUR NUMBER) such that no matter how the set of INTEGERS less than  $[n!e]$  (where  $[x]$  is the FLOOR FUNCTION) is partitioned into  $k$  classes, one class must contain INTEGERS  $x, y, z$  such that  $x + y = z$ , where  $x$  and  $y$  are not necessarily distinct. The upper bound has since been slightly improved to  $[n!(e - 1/24)]$ .

References

- Guy, R. K. “Schur's Problem. Partitioning Integers into Sum-Free Classes” and “The Modular Version of Schur's Problem.” §E11 and E12 in *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 209–212, 1994.

**Schur Matrix**

The  $p \times p$  SQUARE MATRIX formed by setting  $s_{ij} = \xi^{ij}$ , where  $\xi$  is an  $p$ th ROOT OF UNITY. The Schur matrix has a particularly simple DETERMINANT given by

$$\det S = \epsilon_p p^{p/2},$$

where  $p$  is an ODD PRIME and

$$\epsilon_p \equiv \begin{cases} 1 & \text{if } p \equiv 1 \pmod{4} \\ i & \text{if } p \equiv 3 \pmod{4}. \end{cases}$$

This determinant has been used to prove the QUADRATIC RECIPROCITY LAW (Landau 1958, Vardi 1991). The ABSOLUTE VALUES of the PERMANENTS of the Schur matrix of order  $2p + 1$  are given by 1, 3, 5, 105, 81, 6765, ... (Sloane's A003112, Vardi 1991).

Denote the Schur matrix  $S_p$  with the first row and first row column omitted by  $S'_p$ . Then

$$\text{perm } S_p = p \text{ perm } S'_p,$$

where perm denoted the PERMANENT (Vardi 1991).

**Schur Multiplier**

A property of FINITE SIMPLE GROUPS which is known for all such GROUPS.

see also FINITE GROUP, SIMPLE GROUP

**Schur Number**

The Schur numbers are the numbers in the partitioning of a set which are guaranteed to exist by SCHUR'S LEMMA. Schur numbers satisfy the inequality

$$s(k) \geq c(315)^{k/5}$$

for  $k > 5$  and some constant  $c$ . SCHUR'S THEOREM also shows that

$$s(n) \leq R(n),$$

where  $R(n)$  is a RAMSEY NUMBER. The first few Schur numbers are 1, 4, 13, 44, ( $\geq 157$ ), ... (Sloane's A045652).

see also RAMSEY NUMBER, RAMSEY'S THEOREM, SCHUR'S LEMMA, SCHUR'S THEOREM

References

Sloane, N. J. A. Sequence A045652 in "An On-Line Version of the Encyclopedia of Integer Sequences."

### Schur's Problem

see SCHUR'S LEMMA

### Schur's Representation Lemma

If  $\pi$  on  $V$  and  $\pi'$  on  $V'$  are irreducible representations and  $E : V \rightarrow V'$  is a linear map such that  $\pi'(g)E = E\pi(g)$  for all  $g \in$  and group  $G$ , then  $E = 0$  or  $E$  is invertible. Furthermore, if  $V = V'$ , then  $E$  is a SCALAR.

### References

Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537–549, 1996.

### Schur's Theorem

As shown by Schur in 1916, the SCHUR NUMBER  $s(n)$  satisfies

$$s(n) \leq R(n)$$

for  $n = 1, 2, \dots$ , where  $R(n)$  is a RAMSEY NUMBER.

see also RAMSEY NUMBER, SCHUR'S LEMMA, SCHUR NUMBER

### Schwarz's Inequality

$$|\langle \psi_1 | \psi_2 \rangle|^2 \leq \langle \psi_1 | \psi_1 \rangle \langle \psi_2 | \psi_2 \rangle. \quad (1)$$

Written out explicitly

$$\left[ \int_a^b \psi_1(x) \psi_2(x) dx \right]^2 \leq \int_a^b [\psi_1(x)]^2 dx \int_a^b [\psi_2(x)]^2 dx, \quad (2)$$

with equality IFF  $g(x) = \alpha f(x)$  with  $\alpha$  a constant. To derive, let  $\psi(x)$  be a COMPLEX function and  $\lambda$  a COMPLEX constant such that  $\psi(x) \equiv f(x) + \lambda g(x)$  for some  $f$  and  $g$ . Then

$$\begin{aligned} \int \psi^* \psi dx &= \int f^* f dx + \lambda \int f^* g dx + \lambda^* \int g^* f dx \\ &\quad + \lambda \lambda^* \int g^* g dx \geq 0, \quad (3) \end{aligned}$$

with equality when  $\psi(x) = 0$ . Now, note that  $\lambda$  and  $\lambda^*$  are LINEARLY INDEPENDENT (they are ORTHOGONAL), so differentiate with respect to one of them (say  $\lambda^*$ ) and set to zero to minimize  $\int \psi^* \psi dx$ .

$$\frac{\partial}{\partial \lambda^*} \int \psi^* \psi dx = \int g^* f dx + \lambda \int g^* g dx = 0 \quad (4)$$

$$\lambda = - \frac{\int g^* f dx}{\int g^* g dx}, \quad (5)$$

which means that

$$\lambda^* = - \frac{\int f^* g dx}{\int g^* g dx}. \quad (6)$$

Plugging back in,

$$\begin{aligned} \int \psi^* \psi dx &= \int f^* f dx - \frac{\int g^* f dx}{\int g^* g dx} \int f^* g dx \\ &\quad - \frac{\int f^* g dx}{\int g^* g dx} \int g^* f dx + \frac{\int g^* f dx \int f^* g dx}{(\int g^* g dx)^2} \int g^* g dx \geq 0. \end{aligned} \quad (7)$$

Multiplying through by  $\int g^* g dx$  gives

$$\begin{aligned} \int f^* f dx \int g^* g dx - \int g^* f dx \int f^* g dx \\ - \int f^* g dx \int g^* f dx + \int g^* f dx \int f^* g dx \geq 0 \end{aligned} \quad (8)$$

$$\int g^* f dx \int f^* g dx \leq \int f^* f dx \int g^* g dx \quad (9)$$

$$\left| \int g^* f dx \right| = \left| \int f^* g dx \right| \leq \int f^* f dx \int g^* g dx \quad (10)$$

or

$$|\langle f | g \rangle|^2 \leq \langle f | f \rangle \langle g | g \rangle. \quad (11)$$

BESSEL'S INEQUALITY can be derived from this.

### References

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 527–529, 1985.

### Schwarz-Pick Lemma

If  $f$  is an analytic map of the DISK  $\mathbb{D}$  into  $\mathbb{D}$  and  $f$  preserves the hyperbolic distance between any two points, then  $f$  is a disk map and preserves all distance.

### References

Busemann, H. *The Geometry of Geodesics*. New York: Academic Press, p. 41, 1955.

**Schwarz Reflection Principle**

Let

$$g(z) \equiv \sum_{n=0}^{\infty} (z - z_0)^n \frac{f^{(n)}(z_0)}{n!}, \quad (1)$$

then

$$\begin{aligned} g^*(z) &= \left[ \sum_{n=0}^{\infty} (z - z_0)^n \frac{f^{(n)}(z_0)}{n!} \right]^* \\ &= \sum_{n=0}^{\infty} (z^* - z_0^*)^n \frac{f^{(n)}(z_0^*)}{n!}. \end{aligned} \quad (2)$$

If  $z_0$  is pure real, then  $z_0 = z_0^*$ , so

$$g^*(z) = \sum_{n=0}^{\infty} (z^* - z_0)^n \frac{f^{(n)}(z_0)}{n!} = g(z^*). \quad (3)$$

Therefore, if a function  $f(z)$  is ANALYTIC over some region including the REAL LINE and  $f(z)$  is REAL when  $z$  is real, then  $f^*(z) = f(z^*)$ .

**Schwarz Triangle**

The Schwarz triangles are SPHERICAL TRIANGLES which, by repeated reflection in their indices, lead to a set of congruent SPHERICAL TRIANGLES covering the SPHERE a finite number of times.

Schwarz triangles are specified by triples of numbers  $(p, q, r)$ . There are four "families" of Schwarz triangles, and the largest triangles from each of these families are

$$(2 \ 2 \ n'), \left(\frac{3}{2} \ \frac{3}{2} \ \frac{3}{2}\right), \left(\frac{3}{2} \ \frac{4}{3} \ \frac{4}{3}\right), \left(\frac{5}{4} \ \frac{5}{4} \ \frac{5}{4}\right).$$

The others can be derived from

$$(p \ q \ r) = (p \ x \ r_1) + (x \ q \ r_2),$$

where

$$\frac{1}{r_1} + \frac{1}{r_2} = \frac{1}{r}$$

and

$$\begin{aligned} \cos\left(\frac{\pi}{x}\right) &= -\cos\left(\frac{\pi}{x'}\right) \\ &= \frac{\cos\left(\frac{\pi}{q}\right) \sin\left(\frac{\pi}{r_1}\right) - \cos\left(\frac{\pi}{p}\right) \sin\left(\frac{\pi}{r_2}\right)}{\sin\left(\frac{\pi}{r}\right)}. \end{aligned}$$

**Schwarz's Triangle Problem**

see FAGNANO'S PROBLEM

**Schwarzian Derivative**

The Schwarzian derivative is defined by

$$D_{\text{Schwarzian}} \equiv \frac{f'''(x)}{f'(x)} - \frac{3}{2} \left[ \frac{f''(x)}{f'(x)} \right]^2.$$

The FEIGENBAUM CONSTANT is universal for 1-D MAPS if its Schwarzian derivative is NEGATIVE in the bounded interval (Tabor 1989, p. 220).

see also FEIGENBAUM CONSTANT

**References**

- Tabor, M. *Chaos and Integrability in Nonlinear Dynamics: An Introduction*. New York: Wiley, 1989.

**Schwenk's Formula**

Let  $R+B$  be the number of MONOCHROMATIC FORCED TRIANGLES (where  $R$  and  $B$  are the number of red and blue TRIANGLES) in an EXTREMAL GRAPH. Then

$$R+B = \binom{n}{3} - \left\lfloor \frac{1}{2}n \left\lfloor \frac{1}{4}(n-1)^2 \right\rfloor \right\rfloor,$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT and  $\lfloor x \rfloor$  is the FLOOR FUNCTION (Schwenk 1972).

see also EXTREMAL GRAPH, MONOCHROMATIC FORCED TRIANGLE

**References**

- Schwenk, A. J. "Acquaintance Party Problem." *Amer. Math. Monthly* **79**, 1113–1117, 1972.

**Scientific Notation**

Scientific notation is the expression of a number  $n$  in the form  $a \times 10^p$ , where

$$p \equiv \lfloor \log_{10} |n| \rfloor$$

is the FLOOR of the base-10 LOGARITHM of  $n$  (the "order of magnitude"), and

$$a \equiv \frac{n}{10^p}$$

is a REAL NUMBER satisfying  $1 \leq |a| < 10$ . For example, in scientific notation, the number  $n = 101,325$  has order of magnitude

$$p = \lfloor \log_{10} 101,325 \rfloor = \lfloor 5.00572 \rfloor = 5,$$

so  $n$  would be written  $1.01325 \times 10^5$ . The special case of 0 does not have a unique representation in scientific notation, i.e.,  $0 = 0 \times 10^0 = 0 \times 10^1 = \dots$

see also CHARACTERISTIC (REAL NUMBER), FIGURES, MANTISSA, SIGNIFICANT FIGURES

## Score Sequence

The score sequence of a TOURNAMENT is a monotonic nondecreasing sequence of the OUTDEGREES of the VERTICES. The score sequences for  $n = 1, 2, \dots$  are 1, 1, 2, 4, 9, 22, 59, 167, ... (Sloane's A000571).

## Screw

A TRANSLATION along a straight line  $L$  and a ROTATION about  $L$  such that the angle of ROTATION is proportional to the TRANSLATION at each instant. Also known as a TWIST.

see also DINI'S SURFACE, HELICOID, ROTATION, SCREW THEOREM, SEASHELL, TRANSLATION

## Screw Theorem

Any motion of a rigid body in space at every instant is a SCREW motion. This theorem was proved by Mozzi and Cauchy.

see also SCREW

## Scruple

An archaic UNIT FRACTION variously defined as  $1/200$  (of an hour),  $1/10$  or  $1/12$  (of an inch),  $1/12$  (of a celestial body's angular diameter), or  $1/60$  (of an hour or DEGREE).

see also CALCUS, UNCIA

## Sea Horse Valley

A portion of the MANDELBROT SET centered around  $-1.25 + 0.047i$  with width approximately  $0.009 + 0.005i$ .

see also MANDELBROT SET

## Searching

Searching refers to locating a given element or an element satisfying certain conditions from some (usually ordered or partially ordered) table, list, TREE, etc.

see also SORTING, TABU SEARCH, TREE SEARCHING

## Search Tree

see TREE SEARCHING

## Seashell

see CONICAL SPIRAL

## Secant

The function defined by  $\sec x \equiv 1/\cos x$ , where  $\cos x$  is the COSINE. The MACLAURIN SERIES of the secant is

$$\sec x = \frac{(-1)^n E_{2n}}{(2n)!} x^{2n} \\ = 1 + \frac{1}{2}x^2 + \frac{5}{24}x^4 + \frac{61}{720}x^6 + \frac{277}{8064}x^8 + \dots,$$

where  $E_{2n}$  is an EULER NUMBER.

see also ALTERNATING PERMUTATION, COSECANT, COSINE, EULER NUMBER, EXSECANT, INVERSE SECANT

## References

- Abramowitz, M. and Stegun, C. A. (Eds.). "Circular Functions." §4.3 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables, 9th printing*. New York: Dover, pp. 71–79, 1972.  
 Spanier, J. and Oldham, K. B. "The Secant  $\sec(x)$  and Cosecant  $\csc(x)$  Functions." Ch. 33 in *An Atlas of Functions*. Washington, DC: Hemisphere, pp. 311–318, 1987.

**Secant Line**

A line joining two points of a curve. In abstract mathematics, the points which a secant line connects can be either REAL or COMPLEX CONJUGATE IMAGINARY.

see also BITANGENT, TANGENT LINE, TRANSVERSAL LINE

**Secant Method**

A ROOT-finding algorithm which assumes a function to be approximately linear in the region of interest. Each improvement is taken as the point where the approximating line crosses the axis. The secant method retains only the most recent estimate, so the root does not necessarily remain bracketed. When the ALGORITHM does converge, its order of convergence is

$$\lim_{k \rightarrow \infty} |\epsilon_{k+1}| \approx C|\epsilon|^\phi, \quad (1)$$

where  $C$  is a constant and  $\phi$  is the GOLDEN MEAN.

$$f'(x_{n-1}) \approx \frac{f(x_{n-1}) - f(x_{n-2})}{x_{n-1} - x_{n-2}} \quad (2)$$

$$f(x_n) \approx f(x_{n-1}) + f'(x_{n-1})(x_n - x_{n-1}) = 0 \quad (3)$$

$$f(x_{n-1}) + \frac{f(x_{n-1}) - f(x_{n-2})}{x_{n-1} - x_{n-2}}(x_n - x_{n-1}) = 0, \quad (4)$$

so

$$x_n = x_{n-1} - \frac{f(x_{n-1})(x_{n-1} - x_{n-2})}{f(x_{n-1}) - f(x_{n-2})}. \quad (5)$$

see also FALSE POSITION METHOD

**Secant Number**

A number, more commonly called an EULER NUMBER, giving the number of ODD ALTERNATING PERMUTATIONS. The term ZAG NUMBER is sometimes also used.

see also ALTERNATING PERMUTATION, EULER NUMBER, EULER ZIGZAG NUMBER, TANGENT NUMBER

**Sech**

see HYPERBOLIC SECANT

**Second**

see ARC SECOND

**Second Curvature**

see TORSION (DIFFERENTIAL GEOMETRY)

**Second Derivative Test**

Suppose  $f(x)$  is a FUNCTION of  $x$  which is twice DIFFERENTIABLE at a STATIONARY POINT  $x_0$ .

1. If  $f''(x_0) > 0$ , then  $f$  has a RELATIVE MINIMUM at  $x_0$ .
2. If  $f''(x_0) < 0$ , then  $f$  has a RELATIVE MAXIMUM at  $x_0$ .

The EXTREMUM TEST gives slightly more general conditions under which functions with  $f''(x_0) = 0$ .

If  $f(x, y)$  is a 2-D FUNCTION which has a RELATIVE EXTREMUM at a point  $(x_0, y_0)$  and has CONTINUOUS PARTIAL DERIVATIVES at this point, then  $f_x(x_0, y_0) = 0$  and  $f_y(x_0, y_0) = 0$ . The second PARTIAL DERIVATIVES test classifies the point as a MAXIMUM or MINIMUM. Define the DISCRIMINANT as

$$D \equiv f_{xx}f_{yy} - f_{xy}f_{yx} = f_{xx}f_{yy} - f_{xy}^2.$$

1. If  $D > 0$ ,  $f_{xx}(x_0, y_0) > 0$  and  $f_{xx}(x_0, y_0) + f_{yy}(x_0, y_0) > 0$ , the point is a RELATIVE MINIMUM.
2. If  $D > 0$ ,  $f_{xx}(x_0, y_0) < 0$ , and  $f_{xx}(x_0, y_0) + f_{yy}(x_0, y_0) < 0$ , the point is a RELATIVE MAXIMUM.
3. If  $D < 0$ , the point is a SADDLE POINT.
4. If  $D = 0$ , higher order tests must be used.

see also DISCRIMINANT (SECOND DERIVATIVE TEST), EXTREMUM, EXTREMUM TEST, FIRST DERIVATIVE TEST, GLOBAL MAXIMUM, GLOBAL MINIMUM, HESSIAN DETERMINANT, MAXIMUM, MINIMUM, RELATIVE MAXIMUM, RELATIVE MINIMUM, SADDLE POINT (FUNCTION)

**Second Fundamental Tensor**

see WEINGARTEN MAP

**Section (Graph)**

A section of a GRAPH is obtained by finding its intersection with a PLANE.

**Section (Pencil)**

The lines of a PENCIL joining the points of a RANGE to another POINT.

see also PENCIL, RANGE (LINE SEGMENT)

**Section (Tangent Bundle)**

A VECTOR FIELD is a section of its TANGENT BUNDLE, meaning that to every point  $x$  in a MANIFOLD  $M$ , a VECTOR  $X(x) \in T_x M$  is associated, where  $T_x$  is the TANGENT SPACE.

see also TANGENT BUNDLE, TANGENT SPACE

**Sectional Curvature**

The mathematical object  $\kappa$  which controls the rate of geodesic deviation.

see also BISHOP'S INEQUALITY, CHEEGER'S FINITENESS THEOREM, GEODESIC

**Sector**

A WEDGE obtained by taking a portion of a CIRCLE with CENTRAL ANGLE  $\theta < \pi$  radians ( $180^\circ$ ), illustrated above as the shaded region. A sector of  $\pi$  radians would be a SEMICIRCLE. Let  $R$  be the radius of the CIRCLE,  $c$  the CHORD length,  $s$  the ARC LENGTH,  $h$  the height of the arced portion, and  $d$  the height of the triangular portion. Then

$$R = h + d \quad (1)$$

$$s = R\theta \quad (2)$$

$$d = R \cos\left(\frac{1}{2}\theta\right) \quad (3)$$

$$= \frac{1}{2}c \cot\left(\frac{1}{2}\theta\right) \quad (4)$$

$$= \frac{1}{2}\sqrt{4R^2 - c^2} \quad (5)$$

$$c = 2R \sin\left(\frac{1}{2}\theta\right) \quad (6)$$

$$= 2d \tan\left(\frac{1}{2}\theta\right) \quad (7)$$

$$= 2\sqrt{R^2 - d^2} \quad (8)$$

$$= 2\sqrt{h(2R - h)}. \quad (9)$$

The ANGLE  $\theta$  obeys the relationships

$$\begin{aligned} \theta &= \frac{s}{R} = 2 \cos^{-1} \left( \frac{d}{R} \right) = 2 \tan^{-1} \left( \frac{c}{2d} \right) \\ &= 2 \sin^{-1} \left( \frac{c}{2R} \right). \end{aligned} \quad (10)$$

The AREA of the sector is

$$A = \frac{1}{2}Rs = \frac{1}{2}R^2\theta \quad (11)$$

(Beyer 1987).

## Segment

A portion of a CIRCLE whose upper boundary is a circular ARC and whose lower boundary is a CHORD making a CENTRAL ANGLE  $\theta < \pi$  radians ( $180^\circ$ ), illustrated above as the shaded region. Let  $R$  be the radius of the CIRCLE,  $c$  the CHORD length,  $s$  the ARC LENGTH,  $h$  the height of the arced portion, and  $d$  the height of the triangular portion. Then

$$R = h + d \quad (1)$$

$$s = R\theta \quad (2)$$

$$d = R \cos\left(\frac{1}{2}\theta\right) \quad (3)$$

$$= \frac{1}{2}c \cot\left(\frac{1}{2}\theta\right) \quad (4)$$

$$= \frac{1}{2}\sqrt{4R^2 - c^2} \quad (5)$$

$$c = 2R \sin\left(\frac{1}{2}\theta\right) \quad (6)$$

$$= 2d \tan\left(\frac{1}{2}\theta\right) \quad (7)$$

$$= 2\sqrt{R^2 - d^2} \quad (8)$$

$$= 2\sqrt{h(2R - h)}. \quad (9)$$

The ANGLE  $\theta$  obeys the relationships

$$\begin{aligned} \theta &= \frac{s}{R} = 2 \cos^{-1}\left(\frac{d}{R}\right) = 2 \tan^{-1}\left(\frac{c}{2d}\right) \\ &= 2 \sin^{-1}\left(\frac{c}{2R}\right). \end{aligned} \quad (10)$$

The AREA of the segment is then

$$A = A_{\text{sector}} - A_{\text{isosceles triangle}} \quad (11)$$

$$= \frac{1}{2}R^2(\theta - \sin \theta) \quad (12)$$

$$= \frac{1}{2}(Rs - cd) \quad (13)$$

$$= R^2 \cos^{-1}\left(\frac{d}{R}\right) - d\sqrt{R^2 - d^2} \quad (14)$$

$$= R^2 \cos^{-1}\left(\frac{R-h}{R}\right) - (R-h)\sqrt{2Rh - h^2}, \quad (15)$$

where the formula for the ISOSCELES TRIANGLE in terms of the VERTEX angle has been used (Beyer 1987).

### Seifert Circle

Eliminate each knot crossing by connecting each of the strands coming into the crossing to the adjacent strand leaving the crossing. The resulting strands no longer cross but form instead a set of nonintersecting CIRCLES called Seifert circles.

#### References

- Adams, C. C. *The Knot Book: An Elementary Introduction to the Mathematical Theory of Knots*. New York: W. H. Freeman, p. 96, 1994.

### Seifert Conjecture

Every smooth NONZERO VECTOR FIELD on the 3-SPHERE has at least one closed orbit. The conjecture was proposed in 1950, proved true for Hopf fibrations, but proved false in general by Kuperberg (1994).

#### References

### Seifert Form

For  $K$  a given KNOT in  $S^3$ , choose a SEIFERT SURFACE  $M^2$  in  $S^3$  for  $K$  and a bicollar  $\hat{M} \times [-1, 1]$  in  $S^3 - K$ . If  $x \in H_1(\hat{M})$  is represented by a 1-cycle in  $\hat{M}$ , let  $x^+$

denote the homology cycle carried by  $x \times 1$  in the bicollar. Similarly, let  $x^-$  denote  $x \times -1$ . The function  $f : H_1(\hat{M}) \times H_1(\hat{M}) \rightarrow \mathbb{Z}$  defined by

$$f(x, y) = \text{lk}(x, y^+),$$

where  $\text{lk}$  denotes the LINKING NUMBER, is called a Seifert form for  $K$ .

see also SEIFERT MATRIX

#### References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, pp. 200–201, 1976.

### Seifert Matrix

Given a SEIFERT FORM  $f(x, y)$ , choose a basis  $e_1, \dots, e_{2g}$  for  $H_1(\hat{M})$  as a  $\mathbb{Z}$ -module so every element is uniquely expressible as

$$n_1 e_1 + \dots + n_{2g} e_{2g}$$

with  $n_i$  integer, define the Seifert matrix  $V$  as the  $2g \times 2g$  integral MATRIX with entries

$$v_{ij} = \text{lk}(e_i, e_j^+).$$

The right-hand TREFOIL KNOT has Seifert matrix

$$V = \begin{bmatrix} -1 & 1 \\ 0 & -1 \end{bmatrix}.$$

A Seifert matrix is not a knot invariant, but it can be used to distinguish between different SEIFERT SURFACES for a given knot.

see also ALEXANDER MATRIX

#### References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, pp. 200–203, 1976.

### Seifert's Spherical Spiral

Is given by the CYLINDRICAL COORDINATES parametric equation

$$r = \text{sn}(s)$$

$$\theta = ks$$

$$z = \text{cn}(s),$$

where  $k$  is a POSITIVE constant and  $\text{sn}(s)$  and  $\text{cn}(s)$  are JACOBI ELLIPTIC FUNCTIONS (Whittaker and Watson 1990, pp. 527–528).

#### References

- Bowman, F. *Introduction to Elliptic Functions, with Applications*. New York: Dover, p. 34, 1961.  
 Whittaker, E. T. and Watson, G. N. *A Course in Modern Analysis, 4th ed.* Cambridge, England: Cambridge University Press, 1990.

### Seifert Surface

An orientable surface with one boundary component such that the boundary component of the surface is a given KNOT  $K$ . In 1934, Seifert proved that such a surface can be constructed for any KNOT. The process of generating this surface is known as Seifert's algorithm. Applying Seifert's algorithm to an alternating projection of an alternating knot yields a Seifert surface of minimal GENUS.

There are KNOTS for which the minimal genus Seifert surface cannot be obtained by applying Seifert's algorithm to any projection of that KNOT, as proved by Morton in 1986 (Adams 1994, p. 105).

see also GENUS (KNOT), SEIFERT MATRIX

#### References

 Seifert, H. "Über das Geschlecht von Knotten." *Math. Ann.* **110**, 571–592, 1934.

### Self-Adjoint Matrix

A MATRIX  $A$  for which

$$A^\dagger \equiv (A^T)^* = A,$$

where the ADJOINT OPERATOR is denoted  $A^\dagger$ ,  $A^T$  is the MATRIX TRANSPOSE, and  $*$  is the COMPLEX CONJUGATE. If a MATRIX is self-adjoint, it is said to be HERMITIAN.

see also ADJOINT OPERATOR, HERMITIAN MATRIX, MATRIX TRANSPOSE

### Self-Adjoint Operator

Given a differential equation

$$\tilde{\mathcal{L}}u(x) \equiv p_0 \frac{du^2}{dx^2} + p_1 \frac{du}{dx} + p_2 u, \quad (1)$$

where  $p_i \equiv p_i(x)$  and  $u \equiv u(x)$ , the ADJOINT OPERATOR  $\tilde{\mathcal{L}}^\dagger$  is defined by

$$\begin{aligned} \tilde{\mathcal{L}}^\dagger u &\equiv \frac{d}{dx^2}(p_0 u) - \frac{d}{dx}(p_1 u) + p_2 u \\ &= p_0 \frac{d^2 u}{dx^2} + (2p_0' - p_1) \frac{du}{dx} + (p_0'' - p_1' + p_2)u. \end{aligned} \quad (2)$$

In order for the operator to be self-adjoint, i.e.,

$$\tilde{\mathcal{L}} = \tilde{\mathcal{L}}^\dagger, \quad (4)$$

the second terms in (1) and (3) must be equal, so

$$p_0'(x) = p_1(x). \quad (5)$$

This also guarantees that the third terms are equal, since

$$p_0'(x) = p_1(x) \Rightarrow p_0''(x) = p_1'(x), \quad (6)$$

so (3) becomes

$$\tilde{\mathcal{L}}u = \tilde{\mathcal{L}}^\dagger u = p_0 \frac{d^2}{dx^2} + p_0' \frac{du}{dx} + p_2 u \quad (7)$$

$$= \frac{d}{dx} \left( p_0 \frac{du}{dx} \right) + p_2 u = 0. \quad (8)$$

The LEGENDRE DIFFERENTIAL EQUATION and the equation of SIMPLE HARMONIC MOTION are self-adjoint, but the LAGUERRE DIFFERENTIAL EQUATION and HERMITE DIFFERENTIAL EQUATION are not.

A nonself-adjoint second-order linear differential operator can always be transformed into a self-adjoint one using STURM-LIOUVILLE THEORY. In the special case  $p_2(x) = 0$ , (8) gives

$$\frac{d}{dx} \left[ p_0(x) \frac{du}{dx} \right] = 0 \quad (9)$$

$$p_0(x) \frac{du}{dx} = C \quad (10)$$

$$du = C \frac{dx}{p_0(x)} \quad (11)$$

$$u = C \int \frac{dx}{p_0(x)}, \quad (12)$$

where  $C$  is a constant of integration.

A self-adjoint operator which satisfies the BOUNDARY CONDITIONS

$$v^* p U'|_{x=a} = v^* p U'|_{x=b} \quad (13)$$

is automatically a HERMITIAN OPERATOR.

see also ADJOINT OPERATOR, HERMITIAN OPERATOR, STURM-LIOUVILLE THEORY

#### References

**Self-Avoiding Walk**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let the number of RANDOM WALKS on a  $d$ -D lattice starting at the ORIGIN which never land on the same lattice point twice in  $n$  steps be denoted  $c(n)$ . The first few values are

$$c_d(0) = 1 \quad (1)$$

$$c_d(1) = 2d \quad (2)$$

$$c_d(2) = 2d(2d-1). \quad (3)$$

The connective constant

$$\mu_d \equiv \lim_{n \rightarrow \infty} [c_d(n)]^{1/n} \quad (4)$$

is known to exist and be FINITE. The best ranges for these constants are

$$\mu_2 \in [2.62002, 2.6939] \quad (5)$$

$$\mu_3 \in [4.572140, 4.7476] \quad (6)$$

$$\mu_4 \in [6.742945, 6.8179] \quad (7)$$

$$\mu_5 \in [8.828529, 8.8602] \quad (8)$$

$$\mu_6 \in [10.874038, 10.8886] \quad (9)$$

(Finch).

For the triangular lattice in the plane,  $\mu < 4.278$  (Alm 1993), and for the hexagonal planar lattice, it is conjectured that

$$\mu = \sqrt{2 + \sqrt{2}} \quad (10)$$

(Madras and Slade 1993).

The following limits are also believed to exist and to be FINITE:

$$\begin{cases} \lim_{n \rightarrow \infty} \frac{c(n)}{\mu^n n^{\gamma-1}} & \text{for } d \neq 4 \\ \lim_{n \rightarrow \infty} \frac{c(n)}{\mu^n n^{\gamma-1} (\ln n)^{1/4}} & \text{for } d = 4, \end{cases} \quad (11)$$

where the critical exponent  $\gamma = 1$  for  $d > 4$  (Madras and Slade 1993) and it has been conjectured that

$$\gamma = \begin{cases} \frac{43}{32} & \text{for } d = 2 \\ 1.162\dots & \text{for } d = 3 \\ 1 & \text{for } d = 4. \end{cases} \quad (12)$$

Define the mean square displacement over all  $n$ -step self-avoiding walks  $\omega$  as

$$s(n) \equiv \langle |\omega(n)|^2 \rangle = \frac{1}{c(n)} \sum_{\omega} |\omega(n)|^2. \quad (13)$$

The following limits are believed to exist and be FINITE:

$$\begin{cases} \lim_{n \rightarrow \infty} \frac{s(n)}{n^{2\nu}} & \text{for } d \neq 4 \\ \lim_{n \rightarrow \infty} \frac{s(n)}{n^{2\nu} (\ln n)^{1/4}} & \text{for } d = 4, \end{cases} \quad (14)$$

where the critical exponent  $\nu = 1/2$  for  $d > 4$  (Madras and Slade 1993), and it has been conjectured that

$$\nu = \begin{cases} \frac{3}{4} & \text{for } d = 2 \\ 0.59\dots & \text{for } d = 3 \\ \frac{1}{2} & \text{for } d = 4. \end{cases} \quad (15)$$

**Self-Conjugate Subgroup**

see INVARIANT SUBGROUP

**Self-Descriptive Number**

A 10-DIGIT number satisfying the following property. Number the DIGITS 0 to 9, and let DIGIT  $n$  be the number of  $n$ s in the number. There is exactly one such number: 6210001000.

**References**

**Self-Homologous Point**

see SIMILITUDE CENTER

**Self Number**

A number (usually base 10 unless specified otherwise) which has no GENERATOR. Such numbers were originally called COLUMBIAN NUMBERS (S. 1974). There are infinitely many such numbers, since an infinite sequence of self numbers can be generated from the RECURRENCE RELATION

$$C_k = 8 \cdot 10^{k-1} + C_{k-1} + 8, \quad (1)$$

for  $k = 2, 3, \dots$ , where  $C_1 = 9$ . The first few self numbers are 1, 3, 5, 7, 9, 20, 31, 42, 53, 64, 75, 86, 97, ... (Sloane's A003052).

An infinite number of 2-self numbers (i.e., base-2 self numbers) can be generated by the sequence

$$C_k = 2^j + C_{k-1} + 1 \quad (2)$$

for  $k = 1, 2, \dots$ , where  $C_1 = 1$  and  $j$  is the number of digits in  $C_{k-1}$ . An infinite number of  $n$ -self numbers can be generated from the sequence

$$C_k = (n-2)n^{k-1} + C_{k-1} + (n-2) \quad (3)$$

for  $k = 2, 3, \dots$ , and

$$C_1 = \begin{cases} n-1 & \text{for } n \text{ even} \\ n-2 & \text{for } n \text{ odd.} \end{cases} \quad (4)$$

Joshi (1973) proved that if  $k$  is ODD, then  $m$  is a  $k$ -self number IFF  $m$  is ODD. Patel (1991) proved that  $2k$ ,  $4k+2$ , and  $k^2+2k+1$  are  $k$ -self numbers in every EVEN base  $k \geq 4$ .

#### Self-Reciprocating Property

Let  $h$  be the number of sides of certain skew POLYGONS (Coxeter 1973, p. 15). Then

$$h = \frac{2(p+q+2)}{10-p-q}.$$

#### References

- Coxeter, H. S. M. *Regular Polytopes*, 3rd ed. New York: Dover, 1973.

#### Self-Recursion

Self-recursion is a RECURSION which is defined in terms of itself, resulting in an ill-defined infinite regress.

see SELF-RECURSION

#### Self-Similarity

An object is said to be self-similar if it looks "roughly" the same on any scale. FRACTALS are a particularly interesting class of self-similar objects.

see also FRACTAL

#### References

- Hutchinson, J. "Fractals and Self-Similarity." *Indiana Univ. J. Math.* **30**, 713–747, 1981.

#### Self-Transversality Theorem

Let  $j$ ,  $r$ , and  $s$  be distinct INTEGERS (mod  $n$ ), and let  $W_i$  be the point of intersection of the side or diagonal  $V_i V_{i+j}$  of the  $n$ -gon  $P = [V_1, \dots, V_n]$  with the transversal  $V_{i+r} V_{i+s}$ . Then a NECESSARY and SUFFICIENT condition for

$$\prod_{i=1}^n \left[ \frac{V_i W_i}{W_i V_{i+j}} \right] = (-1)^n,$$

where  $AB||CD$  and

$$\left[ \frac{AB}{CD} \right],$$

is the ratio of the lengths  $[A, B]$  and  $[C, D]$  with a plus or minus sign depending on whether these segments have the same or opposite direction, is that

1.  $n = 2m$  is EVEN with  $j \equiv m \pmod{n}$  and  $s \equiv r + m \pmod{n}$ ,
2.  $n$  is arbitrary and either  $s \equiv 2r$  and  $j \equiv 3r$ , or
3.  $r \equiv 2s \pmod{n}$  and  $j \equiv 3s \pmod{n}$ .

#### References

- Grünbaum, B. and Shepard, G. C. "Ceva, Menelaus, and the Area Principle." *Math. Mag.* **68**, 254–268, 1995.

#### Selfridge's Conjecture

There exist infinitely many  $n > 0$  with  $p_n^2 > p_{n-i} p_{n+i}$  for all  $i < n$ . Also, there exist infinitely many  $n > 0$  such that  $2p_n < p_{n-i} + p_{n+i}$  for all  $i < n$ .

#### Selfridge-Hurwitz Residue

Let the RESIDUE from PÉPIN'S THEOREM be

$$R_n \equiv 3^{(F_n-1)/2} \pmod{F_n},$$

where  $F_n$  is a FERMAT NUMBER. Selfridge and Hurwitz use

$$R_n \pmod{2^{35} - 1, 2^{36}, 2^{36} - 1}.$$

A nonvanishing  $R_n \pmod{2^{36}}$  indicates that  $F_n$  is COMPOSITE for  $n > 5$ .

see also FERMAT NUMBER, PÉPIN'S THEOREM

Marker, D. "Model Theory and Exponentiation." *Not. Amer. Math. Soc.* **43**, 753–759, 1996.

**Semianalytic**

$X \subseteq \mathbb{R}^n$  is semianalytic if, for all  $x \in \mathbb{R}^n$ , there is an open neighborhood  $U$  of  $x$  such that  $X \cap U$  is a finite Boolean combination of sets  $\{\bar{x} \in U : f(\bar{x}) = 0\}$  and  $\{\bar{x} \in U : g(\bar{x}) > 0\}$ , where  $f, g : U \rightarrow \mathbb{R}$  are ANALYTIC.

see also ANALYTIC FUNCTION, PSEUDOANALYTIC FUNCTION, SUBANALYTIC

**References**

Marker, D. "Model Theory and Exponentiation." *Not. Amer. Math. Soc.* **43**, 753–759, 1996.

**Semicircle**

Half a CIRCLE. The PERIMETER of the semicircle of RADIUS  $r$  is

$$L = 2r + \pi r = r(2 + \pi), \quad (1)$$

and the AREA is

$$A = 2 \int_0^r \sqrt{r^2 - y^2} dy = \frac{1}{2} \pi r^2. \quad (2)$$

The weighted mean of  $y$  is

$$\langle y \rangle = 2 \int_0^r y \sqrt{r^2 - y^2} dy = \frac{2}{3} r^3. \quad (3)$$

The CENTROID is then given by

$$\bar{y} = \frac{\langle y \rangle}{A} = \frac{4r}{3\pi}. \quad (4)$$

The semicircle is the CROSS-SECTION of a HEMISPHERE for any PLANE through the  $z$ -AXIS.

**Semicolon Derivative**

see COVARIANT DERIVATIVE

**Semiconvergent Series**

see ASYMPTOTIC SERIES

**Semicubical Parabola**

A PARABOLA-like curve with Cartesian equation

$$y = ax^{3/2}, \quad (1)$$

parametric equations

$$x = t^2 \quad (2)$$

$$y = at^3, \quad (3)$$

and POLAR COORDINATES,

$$r = \frac{\tan^2 \theta \sec \theta}{a}. \quad (4)$$

The semicubical parabola is the curve along which a particle descending under gravity describes equal vertical spacings within equal times, making it an ISOCHRONOUS CURVE. The problem of finding the curve having this property was posed by Leibniz in 1687 and solved by Huygens (MacTutor Archive).

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = \frac{1}{27} (4 + 9t^2)^{3/2} - \frac{8}{27} \quad (5)$$

$$\kappa(t) = \frac{6}{t(4 + 9t^2)^{3/2}} \quad (6)$$

$$\phi(t) = \tan^{-1}(\frac{3}{2}t). \quad (7)$$

Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics*. Cambridge, MA: MIT Press, p. 613, 1980.

**Semiflow**

An ACTION with  $G = \mathbb{R}^+$ .

see also FLOW

**Semigroup**

A mathematical object defined for a set and a BINARY OPERATOR in which the multiplication operation is ASSOCIATIVE. No other restrictions are placed on a semigroup; thus a semigroup need not have an IDENTITY ELEMENT and its elements need not have inverses within the semigroup. A semigroup is an ASSOCIATIVE GROUPOID.

A semigroup can be empty. The total number of semigroups of order  $n$  are 1, 4, 18, 126, 1160, 15973, 836021, ... (Sloane's A001423). The number of semigroups of order  $n$  with one IDEMPOTENT are 1, 2, 5, 19, 132, 3107, 623615, ... (Sloane's A002786), and with two IDEMPOTENTS are 2, 7, 37, 216, 1780, 32652, ... (Sloane's A002787). The number  $a(n)$  of semigroups having  $n$  IDEMPOTENTS are 1, 2, 6, 26, 135, 875, ... (Sloane's A002788).

see also ASSOCIATIVE, BINARY OPERATOR, FREE SEMIGROUP, GROUPOID, INVERSE SEMIGROUP, MONOID, QUASIGROUP

**References**

**Semilatus Rectum**

Given an ELLIPSE, the semilatus rectum is defined as the distance  $L$  measured from a FOCUS such that

$$\frac{1}{L} \equiv \frac{1}{2} \left( \frac{1}{r_+} + \frac{1}{r_-} \right), \quad (1)$$

where  $r_+ = a(1+e)$  and  $r_- = a(1-e)$  are the APOAPSIS and PERIAPSIS, and  $e$  is the ELLIPSE's ECCENTRICITY. Plugging in for  $r_+$  and  $r_-$  then gives

$$\begin{aligned} \frac{1}{L} &= \frac{1}{2a} \left( \frac{1}{1-e} + \frac{1}{1+e} \right) = \frac{1}{2a} \frac{(1+e) + (1-e)}{1-e^2} \\ &= \frac{1}{a} \frac{1}{1-e^2}, \end{aligned} \quad (2)$$

so

$$L = a(1-e^2). \quad (3)$$

see also ECCENTRICITY, ELLIPSE, FOCUS, LATUS RECTUM, SEMIMAJOR AXIS, SEMIMINOR AXIS

**Semimagic Square**

A square that fails to be a MAGIC SQUARE only because one or both of the main diagonal sums do not equal the MAGIC CONSTANT is called a SEMIMAGIC SQUARE.

see also MAGIC SQUARE

**Semimajor Axis**

HALF the distance across an ELLIPSE along its long principal axis.

see also ELLIPSE, SEMIMINOR AXIS

**Semiminor Axis**

Half the distance across an ELLIPSE along its short principal axis.

see also ELLIPSE, SEMIMAJOR AXIS

**Semiperfect Magic Cube**

A semiperfect magic cube, also called an ANDREWS CUBE, is a MAGIC CUBE for which the cross-section diagonals do not sum to the MAGIC CONSTANT.

see also MAGIC CUBE, PERFECT MAGIC CUBE

**References**

Gardner, M. “Magic Squares and Cubes.” Ch. 17 in *Time Travel and Other Mathematical Bewilderments*. New York: W. H. Freeman, pp. 213–225, 1988.

**Semiperfect Number**

A number such as  $20 = 1 + 4 + 5 + 10$  which is the SUM of some (or all) its PROPER DIVISORS. A semiperfect number which is the SUM of *all* its PROPER DIVISORS is called a PERFECT NUMBER. The first few semiperfect numbers are 6, 12, 18, 20, 24, 28, 30, 36, 40, ... (Sloane's A005835). Every multiple of a semiperfect number is semiperfect, as are all numbers  $2^m p$  for  $m \geq 1$  and  $p$  a PRIME between  $2^m$  and  $2^{m+1}$  (Guy 1994, p. 47).

A semiperfect number cannot be DEFICIENT. Rare ABUNDANT NUMBERS which are not semiperfect are called WEIRD NUMBERS. Semiperfect numbers are sometimes also called PSEUDOPERFECT NUMBERS.

see also ABUNDANT NUMBER, DEFICIENT NUMBER, PERFECT NUMBER, PRIMITIVE SEMIPERFECT NUMBER, WEIRD NUMBER

### Semiperimeter

The semiperimeter on a figure is defined as

$$s \equiv \frac{1}{2}p, \quad (1)$$

where  $p$  is the PERIMETER. The semiperimeter of POLYGONS appears in unexpected ways in the computation of their AREAS. The most notable cases are in the ALTITUDE, EXRADIUS, and INRADIUS of a TRIANGLE, the SODDY CIRCLES, HERON'S FORMULA for the AREA of a TRIANGLE in terms of the legs  $a$ ,  $b$ , and  $c$

$$A_{\Delta} = \sqrt{s(s-a)(s-b)(s-c)}, \quad (2)$$

and BRAHMAGUPTA'S FORMULA for the AREA of a QUADRILATERAL

$$A_{\text{quadrilateral}} = \sqrt{(s-a)(s-b)(s-c)(s-d) - abcd \cos^2 \left( \frac{A+B}{2} \right)}. \quad (3)$$

The semiperimeter also appears in the beautiful L'HUIER'S THEOREM about SPHERICAL TRIANGLES.

For a TRIANGLE, the following identities hold,

$$s - a = \frac{1}{2}(-a + b + c) \quad (4)$$

$$s - b = \frac{1}{2}(a + b - c) \quad (5)$$

$$s - c = \frac{1}{2}(a + b - c). \quad (6)$$

Now consider the above figure. Let  $I$  be the INCENTER of the TRIANGLE  $\Delta ABC$ , with  $D$ ,  $E$ , and  $F$  the tangent points of the INCIRCLE. Extend the line  $BA$  with  $GA = CE$ . Note that the pairs of triangles  $(ADI, AFI)$ ,  $(BDI, BEI)$ ,  $(CFI, CEI)$  are congruent. Then

$$\begin{aligned} BG &= BD + AD + AG = BD + AD + CE \\ &= \frac{1}{2}(2BD + 2AD + 2CE) \\ &= \frac{1}{2}[(BD + BE) + (AD + AF) + (CE + CF)] \\ &= \frac{1}{2}[(BD + AD) + (BE + CE) + (AF + CF)] \\ &= \frac{1}{2}(AB + BC + AC) = \frac{1}{2}(a + b + c) = s. \end{aligned} \quad (7)$$

Furthermore,

$$\begin{aligned} s - a &= BG - BC \\ &= (BD + AD + AG) - (BE + CE) \\ &= (BD + AD + CE) - (BD + CE) = AC \quad (8) \\ s - b &= BG - AC \\ &= (BD + AD + AG) - (AF + CF) \\ &= (BD + AD + CE) - (AD + CE) = BD \quad (9) \\ s - c &= BG - AB = AG \quad (10) \end{aligned}$$

(Dunham 1990). These equations are some of the building blocks of Heron's derivation of HERON'S FORMULA.

#### References

- Dunham, W. "Heron's Formula for Triangular Area." Ch. 5 in *Journey Through Genius: The Great Theorems of Mathematics*. New York: Wiley, pp. 113-132, 1990.

### Semiprime

A COMPOSITE number which is the PRODUCT of two PRIMES (possibly equal). They correspond to the 2-ALMOST PRIMES. The first few are 4, 6, 9, 10, 14, 15, 21, 22, ... (Sloane's A001358).

see also ALMOST PRIME, CHEN'S THEOREM, COMPOSITE NUMBER, PRIME NUMBER

#### References

- Sloane, N. J. A. Sequence A001358/M3274 in "An On-Line Version of the Encyclopedia of Integer Sequences."

### Semiprime Ring

Given an IDEAL  $A$ , a semiprime ring is one for which  $A^n = 0$  IMPLIES  $A = 0$  for any POSITIVE  $n$ . Every PRIME RING is semiprime.

see also PRIME RING

### Semiregular Polyhedron

A POLYHEDRON or plane TESSELLATION is called semiregular if its faces are all REGULAR POLYGONS and its corners are alike (Walsh 1972; Coxeter 1973, pp. 4 and 58; Holden 1991, p. 41). The usual name for a semiregular polyhedron is an ARCHIMEDEAN SOLIDS, of which there are exactly 13.

see also ARCHIMEDEAN SOLID, POLYHEDRON, TESSELLATION

#### References

### Semiring

A semiring is a set together with two BINARY OPERATORS  $S(+, *)$  satisfying the following conditions:

1. Additive associativity: For all  $a, b, c \in S$ ,  $(a+b)+c = a+(b+c)$ ,
2. Additive commutativity: For all  $a, b \in S$ ,  $a+b = b+a$ ,
3. Multiplicative associativity: For all  $a, b, c \in S$ ,  $(a*b)*c = a*(b*c)$ ,
4. Left and right distributivity: For all  $a, b, c \in S$ ,  $a*(b+c) = (a*b)+(a*c)$  and  $(b+c)*a = (b*a)+(c*a)$ .

Thus a semiring is therefore a commutative SEMIGROUP under addition and a SEMIGROUP under multiplication. A semiring can be empty.

see also BINARY OPERATOR, RING, RINGOID, SEMIGROUP

#### References

- Rosenfeld, A. *An Introduction to Algebraic Structures*. New York: Holden-Day, 1968.

### Semisecant

see TRANSVERSAL LINE

### Semisimple

A  $p$ -ELEMENT  $x$  of a GROUP  $G$  is semisimple if  $E(C_G(x)) \neq 1$ , where  $E(H)$  is the commuting product of all components of  $H$  and  $C_G(x)$  is the CENTRALIZER of  $G$ .

see also CENTRALIZER,  $p$ -ELEMENT

### Semisimple Algebra

An ALGEBRA with no nontrivial nilpotent IDEALS. In the 1890s, Cartan, Frobenius, and Molien independently proved that any finite-dimensional semisimple algebra over the REAL or COMPLEX numbers is a finite and unique DIRECT SUM of SIMPLE ALGEBRAS. This result was then extended to algebras over arbitrary fields by Wedderburn in 1907 (Kleiner 1996).

see also IDEAL, NILPOTENT ELEMENT, SIMPLE ALGEBRA

#### References

- Kleiner, I. "The Genesis of the Abstract Ring Concept." *Amer. Math. Monthly* **103**, 417–424, 1996.

### Semisimple Lie Group

A LIE GROUP which has a simply connected covering group HOMEOMORPHIC to  $\mathbb{R}^n$ . The prototype is any connected closed subgroup of upper TRIANGULAR COMPLEX MATRICES. The HEISENBERG GROUP is such a group.

see also HEISENBERG GROUP, LIE GROUP

#### References

- Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537–549, 1996.

### Semisimple Ring

A SEMIPRIME RING which is also an ARTINIAN RING.

see also ARTINIAN RING

### Semistable

When a PRIME  $l$  divides the DISCRIMINANT of a ELLIPTIC CURVE  $E$ , two or all three roots of  $E$  become congruent mod  $l$ . An ELLIPTIC CURVE is semistable if, for all such PRIMES  $l$ , only two roots become CONGRUENT mod  $l$  (with more complicated definitions for  $p = 2$  or 3).

see also DISCRIMINANT (ELLIPTIC CURVE), ELLIPTIC CURVE

### Sensitivity

The probability that a STATISTICAL TEST will be positive for a true statistic.

see also SPECIFICITY, STATISTICAL TEST, TYPE I ERROR, TYPE II ERROR

### Sentence

A LOGIC FORMULA with no FREE variables.

### Separating Edge

An EDGE of a GRAPH is separating if a path from a point  $A$  to a point  $B$  must pass over it. Separating EDGES can therefore be viewed as either bridges or dead ends.

see also EDGE (GRAPH)

### Separating Family

A SEPARATING FAMILY is a SET of SUBSETS in which each pair of adjacent elements are found separated, each in one of two disjoint subsets. The 26 letters of the alphabet can be separated by a family of 9,

$(abcdefghi)$	$(jklmnopqr)$	$(stuvwxyz)$
$(abcjklstu)$	$(defmnovwx)$	$(ghipqryz)$
$(adgjmpsvy)$	$(behkngtwz)$	$(cfilorux)$

The minimal size of the separating family for an  $n$ -set is 0, 2, 3, 4, 5, 5, 6, 6, 6, 7, 7, 7, ... (Sloane's A007600).

### Separation

Two distinct point pairs  $AC$  and  $BD$  separate each other if  $A$ ,  $B$ ,  $C$ , and  $D$  lie on a CIRCLE (or line) in such order that either of the arcs (or the line segment  $AC$ ) contains one but not both of  $B$  and  $D$ . In addition, the point pairs separate each other if every CIRCLE through  $A$  and  $C$  intersects (or coincides with) every CIRCLE through  $B$  and  $D$ . If the point pairs separate each other, then the symbol  $AC//BD$  is used.

### Separation of Variables

A method of solving partial differential equations in a function  $\Phi$  and variables  $x$ ,  $y$ , ... by making a substitution of the form

$$\Phi(x, y, \dots) \equiv X(x)Y(y)\cdots,$$

breaking the resulting equation into a set of independent ordinary differential equations, solving these for  $X(x)$ ,  $Y(y)$ , ..., and then plugging them back into the original equation.

This technique works because if the product of functions of independent variables is a constant, each function must separately be a constant. Success requires choice of an appropriate coordinate system and may not be attainable at all depending on the equation. Separation of variables was first used by L'Hospital in 1750. It is especially useful in solving equations arising in mathematical physics, such as LAPLACE'S EQUATION, the HELMHOLTZ DIFFERENTIAL EQUATION, and the Schrödinger equation.

see also HELMHOLTZ DIFFERENTIAL EQUATION, LAPLACE'S EQUATION

### Separation Theorem

There exist numbers  $y_1 < y_2 < \dots < x_{n-1}$ ,  $a < y_{n-1}$ ,  $y_{n-1} < b$ , such that

$$\lambda_\nu = \alpha(y_\nu) - \alpha(y_{\nu-1}),$$

where  $\nu = 1, 2, \dots, n$ ,  $y_0 = a$  and  $y_n = b$ . Furthermore, the zeros  $x_1, \dots, x_n$ , arranged in increasing order, alternate with the numbers  $y_1, \dots, y_{n-1}$ , so

$$x_\nu < y_\nu < x_{\nu+1}.$$

More precisely,

$$\begin{aligned} \alpha(x_\nu + \epsilon) - \alpha(a) &< \alpha(y_\nu) - \alpha(a) \\ &= \lambda_1 + \dots + \lambda_\nu < \alpha(x_{\nu+1} - \epsilon) - \alpha(a) \end{aligned}$$

for  $\nu = 1, \dots, n-1$ .

### Separatrix

A phase curve (invariant MANIFOLD) which meets a HYPERBOLIC FIXED POINT (intersection of a stable and an unstable invariant MANIFOLD). A separatrix marks a boundary between phase curves with different properties. For example, the separatrix in the equation of motion for the pendulum occurs at the angular momentum where oscillation gives way to rotation.

### Septendecillion

In the American system,  $10^{54}$ .

see also LARGE NUMBER

### Septillion

In the American system,  $10^{24}$ .

see also LARGE NUMBER

### Sequence

A sequence is an ordered set of mathematical objects which is denoted using braces. For example, the symbol  $\{2n\}_{n=1}^\infty$  denotes the infinite sequence of EVEN NUMBERS  $\{2, 4, \dots, 2n, \dots\}$ .

see also 196-ALGORITHM, A-SEQUENCE, ALCUIN'S SEQUENCE, B2-SEQUENCE, BEATTY SEQUENCE, CARMICHAEL SEQUENCE, CAUCHY SEQUENCE, CONVERGENT SEQUENCE, DEGREE SEQUENCE, DENSITY (SEQUENCE), FRACTAL SEQUENCE, GIUGA SEQUENCE, INFINITIVE SEQUENCE, INTEGER SEQUENCE, ITERATION SEQUENCE, LIST, NONAVERAGING SEQUENCE, PRIMITIVE SEQUENCE, REVERSE-THEN-ADD SEQUENCE, SCORE SEQUENCE, SERIES, SIGNATURE SEQUENCE, SORT-THEN-ADD SEQUENCE, ULAM SEQUENCE

### Sequency

The sequency  $k$  of a WALSH FUNCTION is defined as half the number of zero crossings in the time base.

see also WALSH FUNCTION

### Sequency Function

see WALSH FUNCTION

### Sequential Graph

A CONNECTED GRAPH having  $e$  EDGES is said to be sequential if it is possible to label the nodes  $i$  with distinct INTEGERS  $f_i$  in  $\{0, 1, 2, \dots, e-1\}$  such that when EDGE  $ij$  is labeled  $f_i + f_j$ , the set of EDGE labels is a block of  $e$  consecutive integers (Grace 1983, Gallian 1990). No HARMONIOUS GRAPH is known which cannot also be labeled sequentially.

see also CONNECTED GRAPH, HARMONIOUS GRAPH

### Series

A series is a sum of terms specified by some rule. If each term increases by a constant amount, it is said to be an ARITHMETIC SERIES. If each term equals the previous multiplied by a constant, it is said to be a GEOMETRIC SERIES. A series usually has an INFINITE number of terms, but the phrase INFINITE SERIES is sometimes used for emphasis or clarity.

If the sum of partial sequences comprising the first few terms of the series does not converge to a LIMIT (e.g., it oscillates or approaches  $\pm\infty$ ), it is said to diverge. An example of a convergent series is the GEOMETRIC SERIES

$$\sum_{n=0}^{\infty} \left(\frac{1}{2}\right)^n = 2,$$

and an example of a divergent series is the HARMONIC SERIES

$$\sum_{n=1}^{\infty} \frac{1}{n} = \infty.$$

A number of methods known as CONVERGENCE TESTS can be used to determine whether a given series converges. Although terms of a series can have either sign, convergence properties can often be computed in the "worst case" of all terms being POSITIVE, and then applied to the particular series at hand. A series of terms  $u_n$  is said to be ABSOLUTELY CONVERGENT if the series formed by taking the absolute values of the  $u_n$ ,

$$\sum_n |u_n|,$$

converges.

An especially strong type of convergence is called UNIFORM CONVERGENCE, and series which are uniformly convergent have particularly "nice" properties. For example, the sum of a UNIFORMLY CONVERGENT series of continuous functions is continuous. A CONVERGENT SERIES can be DIFFERENTIATED term by term, provided that the functions of the series have continuous derivatives and that the series of DERIVATIVES is UNIFORMLY CONVERGENT. Finally, a UNIFORMLY CONVERGENT series of continuous functions can be INTEGRATED term by term.

For a table listing the COEFFICIENTS for various series operations, see Abramowitz and Stegun (1972, p. 15).

While it can be difficult to calculate analytical expressions for arbitrary convergent infinite series, many algorithms can handle a variety of common series types.

The program *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) implements many of these algorithms. General techniques also exist for computing the numerical values to any but the most pathological series (Braden 1992).

### Series Reversion

Series reversion is the computation of the COEFFICIENTS of the inverse function given those of the forward function. For a function expressed in a series as

$$y = a_1 x + a_2 x^2 + a_3 x^3 + \dots, \quad (1)$$

the series expansion of the inverse series is given by

$$x = A_1 y + A_2 y^2 + A_3 y^3 + \dots \quad (2)$$

By plugging (2) into (1), the following equation is obtained

$$\begin{aligned} y = & a_1 A_1 y + (a_2 A_1^2 + a_1 A_2) y^2 \\ & + (a_3 A_1^3 + 2a_2 A_1 A_2 + a_1 A_3) y^3 \\ & + (3a_3 A_1^2 A_2 + a_2 A_2^2 + a_2 A_1 A_3) + \dots \end{aligned} \quad (3)$$

Equating COEFFICIENTS then gives

$$A_1 = a_1^{-1} \quad (4)$$

$$A_2 = -\frac{a_2}{a_1} A_1^2 = -a_1^{-3} a_2 \quad (5)$$

$$A_3 = a_1^{-5} (2a_2^2 - a_1 a_3) \quad (6)$$

$$A_4 = a_1^{-7} (5a_1 a_2 a_3 - a_1^2 a_4 - 5a_2^3) \quad (7)$$

$$\begin{aligned} A_5 = & a_1^{-9} (6a_1^2 a_2 a_4 + 3a_1^2 a_2 a_3 + 14a_2^4 - a_1^3 a_5 \\ & - 21a_1 a_2^2 a_3) \end{aligned} \quad (8)$$

$$\begin{aligned} A_6 = & a_1^{-11} (7a_1^3 a_2 a_5 + 7a_1^3 a_3 a_4 + 84a_1 a_2^3 a_3 \\ & - a_1^4 a_6 - 28a_1^2 a_2 a_3^2 - 42a_2^5 - 28a_1^2 a_2^2 a_4) \end{aligned} \quad (9)$$

$$\begin{aligned} A_7 = & a_1^{-13} (8a_1^4 a_2 a_6 + 8a_1^4 a_3 a_5 + 4a_1^4 a_4^2 \\ & + 120a_1^2 a_2^3 a_4 + 180a_1^2 a_2^2 a_3^2 + 132a_2^6 \\ & - a_1^5 a_7 - 36a_1^3 a_2^2 a_5 - 72a_1^3 a_2 a_3 a_4 \\ & - 12a_1^3 a_3^3 - 330a_1 a_2^4 a_3) \end{aligned} \quad (10)$$

(Dwight 1961, Abramowitz and Stegun 1972, p. 16). A derivation of the explicit formula for the  $n$ th term is given by Morse and Feshbach (1953),

$$\begin{aligned} A_n = & \frac{1}{n a_1^n} \sum_{s,t,u,\dots} (-1)^{s+t+u+\dots} \\ & \times \frac{n(n+1)\dots(n-1+s+t+u+\dots)}{s!t!u!\dots} \left(\frac{a_2}{a_1}\right)^s \left(\frac{a_3}{a_1}\right)^t \dots, \end{aligned} \quad (11)$$

where

$$s + 2t + 3u + \dots = n - 1. \quad (12)$$

### Serpentine Curve

A curve named and studied by Newton in 1701 and contained in his classification of CUBIC CURVES. It had been studied earlier by L'Hospital and Huygens in 1692 (MacTutor Archive).

The curve is given by the CARTESIAN equation

$$y(x) = \frac{abx}{x^2 + a^2} \quad (1)$$

and parametric equations

$$x(t) = a \cot t \quad (2)$$

$$y(t) = b \sin t \cos t. \quad (3)$$

The curve has a MAXIMUM at  $x = a$  and a MINIMUM at  $x = -a$ , where

$$y'(x) = \frac{ab(a-x)(a+x)}{(a^2 + x^2)^2} = 0, \quad (4)$$

and inflection points at  $x = \pm\sqrt{3}a$ , where

$$y''(x) = \frac{2abx(x^2 - 3a^2)}{(x^2 + a^2)^3} = 0. \quad (5)$$

The CURVATURE is given by

$$\kappa(x) = \frac{2abx(x^2 - 3a^2)}{(x^2 + a^2)^3 \left[ 1 + \frac{(a^3 b - abx^2)^2}{(x^2 + a^2)^4} \right]^{3/2}} \quad (6)$$

$$\kappa(t) = -\frac{4\sqrt{2}ab[2\cos(2t) - 1]\cot t \csc^2 t}{\{b^2[1 + \cos(4t)] + 2a^2 \csc^4 t\}^{3/2}}. \quad (7)$$

## Serret-Frenet Formulas

see FRENET FORMULAS

## Set

A set is a FINITE or INFINITE collection of objects. Older words for set include AGGREGATE and CLASS. Russell also uses the term MANIFOLD to refer to a set. The study of sets and their properties is the object of SET THEORY. Symbols used to operate on sets include  $\wedge$  (which denotes the EMPTY SET  $\emptyset$ ),  $\vee =$  (which denotes the POWER SET of a set),  $\cap$  (which means “and” or INTERSECTION), and  $\cup$  (which means “or” or UNION).

The NOTATION  $A^B$ , where  $A$  and  $B$  are arbitrary sets, is used to denote the set of MAPS from  $B$  to  $A$ . For example, an element of  $X^{\mathbb{N}}$  would be a MAP from the NATURAL NUMBERS  $\mathbb{N}$  to the set  $X$ . Call such a function  $f$ , then  $f(1)$ ,  $f(2)$ , etc., are elements of  $X$ , so call them  $x_1$ ,  $x_2$ , etc. This now looks like a SEQUENCE of elements of  $X$ , so sequences are really just functions from  $\mathbb{N}$  to  $X$ . This NOTATION is standard in mathematics and is frequently used in symbolic dynamics to denote sequence spaces.

Let  $E$ ,  $F$ , and  $G$  be sets. Then operation on these sets using the  $\cap$  and  $\cup$  operators is COMMUTATIVE

$$E \cap F = F \cap E \quad (1)$$

$$E \cup F = F \cup E, \quad (2)$$

ASSOCIATIVE

$$(E \cap F) \cap G = E \cap (F \cap G) \quad (3)$$

$$A \cap \left( \bigcup_{i=1}^n B_i \right) = \bigcup_{i=1}^n (A \cap B_i) \quad (4)$$

$$(E \cup F) \cup G = E \cup (F \cup G), \quad (5)$$

and DISTRIBUTIVE

$$(E \cap F) \cup G = (E \cup G) \cap (F \cup G) \quad (6)$$

$$(E \cup F) \cap G = (E \cap G) \cup (F \cap G). \quad (7)$$

The proofs follow trivially using VENN DIAGRAMs.

$$P \left( \bigcup_{i=1}^n A_i \right) = \sum_{i=1}^n P(A_i). \quad (8)$$

The table below gives symbols for some common sets in mathematics.

Symbol	Set
$\mathbb{B}^n$	$n$ -ball
$\mathbb{C}$	complex numbers
$C^n, C^{(n)}$	$n$ -differentiable functions
$\mathbb{D}^n$	$n$ -disk
$\mathbb{H}$	quaternions
$\mathbb{I}$	integers
$\mathbb{N}$	natural numbers
$\mathbb{Q}$	rational numbers
$\mathbb{R}^n$	real numbers in $n$ -D
$\mathbb{S}^n$	$n$ -sphere
$\mathbb{Z}$	integers
$\mathbb{Z}_n$	integers (mod $n$ )
$\mathbb{Z}^-$	negative integers
$\mathbb{Z}^+$	positive integers
$\mathbb{Z}^*$	nonnegative integers

see also AGGREGATE, ANALYTIC SET, BOREL SET,  $\mathbb{C}$ , CLASS (SET), COANALYTIC SET, DEFINABLE SET, DERIVED SET, DOUBLE-FREE SET, EXTENSION, GROUND SET,  $\mathbb{I}$ , INTENSION, INTERSECTION, KINNEY'S SET, MANIFOLD,  $\mathbb{N}$ , PERFECT SET, POSET,  $\mathbb{Q}$ ,  $\mathbb{R}$ , SET DIFFERENCE, SET THEORY, TRIPLE-FREE SET, UNION, VENN DIAGRAM, WELL-ORDERED SET,  $\mathbb{Z}$ ,  $\mathbb{Z}^-$ ,  $\mathbb{Z}^+$

## Set Difference

The set difference  $A \setminus B$  is defined by

$$A \setminus B = \{x : x \in A \text{ and } x \notin B\}.$$

The same symbol is also used for QUOTIENT GROUPS.

## Set Partition

A set partition of a SET  $S$  is a collection of disjoint SUBSETS  $B_0, B_1, \dots$  of  $S$  whose UNION is  $S$ , where each  $B_i$  is called a BLOCK. The number of partitions of the SET  $\{k\}_{k=1}^n$  is called a BELL NUMBER.

see also BELL NUMBER, BLOCK, RESTRICTED GROWTH STRING, STIRLING NUMBER OF THE SECOND KIND

## References

Ruskey, F. “Info About Set Partitions.” <http://sue.csc.uvic.ca/~cos/inf/setp/SetPartitions.html>.

## Set Theory

The mathematical theory of SETS. Set theory is closely associated with the branch of mathematics known as LOGIC.

There are a number of different versions of set theory, each with its own rules and AXIOMS. In order of increasing CONSISTENCY STRENGTH, several versions of set theory include PEANO ARITHMETIC (ordinary ALGEBRA), second-order arithmetic (ANALYSIS), ZERMELO-FRAENKEL SET THEORY, Mahlo, weakly

compact, hyper-Mahlo, ineffable, measurable, Ramsey, supercompact, huge, and  $n$ -huge set theory.

Given a set of REAL NUMBERS, there are 14 versions of set theory which can be obtained using only closure and complement (Beeler *et al.* 1972, Item 105).

### Sextillion

In the American system,  $10^{21}$ .

see also LARGE NUMBER

### Sexy Primes

Since a PRIME NUMBER cannot be divisible by 2 or 3, it must be true that, for a PRIME  $p$ ,  $p \equiv 6 \pmod{15}$ . This motivates the definition of sexy primes as a pair of primes  $(p, q)$  such that  $p - q = 6$  ("sexy" since "sex" is the Latin word for "six"). The first few sexy prime pairs are (5, 11), (7, 13), (11, 17), (13, 19), (17, 23), (23, 29), (31, 37), (37, 43), (41, 47), (47, 53), ... (Sloane's A023201 and A046117).

Sexy constellations also exist. The first few sexy triplets (i.e., numbers such that each of  $(p, p + 6, p + 12)$  is PRIME but  $p + 18$  is *not* PRIME) are (7, 13, 19), (17, 23, 29), (31, 37, 43), (47, 53, 59), ... (Sloane's A046118, A046119, and A046120). The first few sexy quadruplets are (11, 17, 23, 29), (41, 47, 53, 59), (61, 67, 73, 79), (251, 257, 263, 269), ... (Sloane's A046121, A046122, A046123, A046124). Sexy quadruplets can only begin with a PRIME ending in a "1." There is only a single sexy quintuplet, (5, 11, 17, 23, 29), since every fifth number of the form  $6n \pm 1$  is divisible by 5, and therefore cannot be PRIME.

**Seydewitz's Theorem**

If a TRIANGLE is inscribed in a CONIC SECTION, any line conjugate to one side meets the other two sides in conjugate points.

see also CONIC SECTION, TRIANGLE

**Sgn**

Also called SIGNUM. It can be defined as

$$\operatorname{sgn} \equiv \begin{cases} -1 & x < 0 \\ 0 & x = 0 \\ 1 & x > 0 \end{cases} \quad (1)$$

or

$$\operatorname{sgn}(x) = 2H(x) - 1, \quad (2)$$

where  $H(x)$  is the HEAVISIDE STEP FUNCTION. For  $x \neq 0$ , this can be written

$$\operatorname{sgn}(x) \equiv \frac{x}{|x|} \text{ for } x \neq 0. \quad (3)$$

see also HEAVISIDE STEP FUNCTION, RAMP FUNCTION

**Shadow**

The SURFACE corresponding to the region of obscuration when a solid is illuminated from a point light source (located at the RADIANT POINT). A DISK is the SHADOW of a SPHERE on a PLANE perpendicular to the SPHERE-RADIANT POINT line. If the PLANE is tilted, the shadow can be the interior of an ELLIPSE or a PARABOLA.

see also PROJECTIVE GEOMETRY

**Shadowing Theorem**

Although a numerically computed CHAOTIC trajectory diverges exponentially from the true trajectory with the same initial coordinates, there exists an errorless trajectory with a slightly different initial condition that stays near ("shadows") the numerically computed one. Therefore, the FRACTAL structure of chaotic trajectories seen in computer maps is real.

**Shah Function**

$$\operatorname{III}(x) \equiv \sum_{n=-\infty}^{\infty} \delta(x-n) \quad (1)$$

where  $\delta(x)$  is the DELTA FUNCTION, so  $\operatorname{III}(x) = 0$  for  $x \notin \mathbb{Z}$  (i.e.,  $x$  not an INTEGER). The shah function obeys the identities

$$\operatorname{III}(ax) = \frac{1}{a} \sum_{n=-\infty}^{\infty} \delta\left(x - \frac{n}{a}\right) \quad (2)$$

$$\operatorname{III}(-x) = \operatorname{III}(x) \quad (3)$$

$$\operatorname{III}(x+n) = \operatorname{III}(x), \quad (4)$$

for  $2n \in \mathbb{Z}$  (i.e.,  $n$  a half-integer).

It is normalized so that

$$\int_{n-1/2}^{n+1/2} \operatorname{III}(x) dx = 1. \quad (5)$$

The "sampling property" is

$$\operatorname{III}(x)f(x) = \sum_{n=-\infty}^{\infty} f(n)\delta(x-n) \quad (6)$$

and the "replicating property" is

$$\operatorname{III}(x) * f(x) = \sum_{n=-\infty}^{\infty} f(x-n), \quad (7)$$

where  $*$  denotes CONVOLUTION.

see also CONVOLUTION, DELTA FUNCTION, IMPULSE PAIR

**Shah-Wilson Constant**

see TWIN PRIMES CONSTANT

**Shallit Constant**

Define  $f(x_1, x_2, \dots, x_n)$  with  $x_i$  POSITIVE as

$$f(x_1, x_2, \dots, x_n) \equiv \sum_{i=1}^n x_i + \sum_{1 \leq i \leq k \leq n} \prod_{j=i}^k \frac{1}{x_j}.$$

Then

$$\min f = 3n - C + o(1)$$

as  $n$  increases, where the Shallit constant is

$$C = 1.369451403937 \dots$$

(Shallit 1995). In their solution, Grosjean and De Meyer (quoted in Shallit 1995) reduced the complexity of the problem.

**Shape Operator**

The negative derivative

$$S(\mathbf{v}) = -D_{\mathbf{v}}\mathbf{N} \quad (1)$$

of the unit normal  $\mathbf{N}$  vector field of a SURFACE is called the shape operator (or WEINGARTEN MAP or SECOND FUNDAMENTAL TENSOR). The shape operator  $S$  is an EXTRINSIC CURVATURE, and the GAUSSIAN CURVATURE is given by the DETERMINANT of  $S$ . If  $\mathbf{x} : U \rightarrow \mathbb{R}^3$  is a REGULAR PATCH, then

$$S(\mathbf{x}_u) = -\mathbf{N}_u \quad (2)$$

$$S(\mathbf{x}_v) = -\mathbf{N}_v. \quad (3)$$

At each point  $\mathbf{p}$  on a REGULAR SURFACE  $M \subset \mathbb{R}^3$ , the shape operator is a linear map

$$S : M_{\mathbf{p}} \rightarrow M_{\mathbf{p}}. \quad (4)$$

The shape operator for a surface is given by the WEINGARTEN EQUATIONS.

see also CURVATURE, FUNDAMENTAL FORMS, WEINGARTEN EQUATIONS

**Shapiro's Cyclic Sum Constant**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Consider the sum

$$f_n(x_1, x_2, \dots, x_n) = \frac{x_1}{x_2 + x_3} + \frac{x_2}{x_3 + x_4} + \dots + \frac{x_{n-1}}{x_n + x_1} + \frac{x_n}{x_1 + x_2}, \quad (1)$$

where the  $x_j$ s are NONNEGATIVE and the DENOMINATORS are POSITIVE. Shapiro (1954) asked if

$$f_n(x_1, x_2, \dots, x_n) \geq \frac{1}{2}n \quad (2)$$

for all  $n$ . It turns out (Mitrinovic *et al.* 1993) that this INEQUALITY is true for all EVEN  $n \leq 12$  and ODD  $n \leq 23$ . Ranikin (1958) proved that for

$$f(n) = \inf_{x \geq 0} f_n(x_1, x_2, \dots, x_n), \quad (3)$$

$$\lambda = \lim_{n \rightarrow \infty} \frac{f(n)}{n} = \inf_{n \geq 1} \frac{f(n)}{n} < \frac{1}{2} - 7 \times 10^{-8}. \quad (4)$$

$\lambda$  can be computed by letting  $\phi(x)$  be the CONVEX HULL of the functions

$$y_1 = e^{-x} \quad (5)$$

$$y_2 = \frac{2}{e^x + e^{x/2}}. \quad (6)$$

Then

$$\lambda = \frac{1}{2}\phi(0) = 0.4945668\dots \quad (7)$$

(Drinfel'd 1971).

A modified sum was considered by Elbert (1973):

$$g_n(x_1, x_2, \dots, x_n) = \frac{x_1 + x_3}{x_1 + x_2} + \frac{x_2 + x_4}{x_2 + x_3} + \dots + \frac{x_{n-1} + x_1}{x_{n-1} + x_n} + \frac{x_n + x_2}{x_n + x_1}. \quad (8)$$

Consider

$$\mu = \lim_{n \rightarrow \infty} \frac{g(n)}{n}, \quad (9)$$

where

$$g(n) = \inf_{x \geq 0} g_n(x_1, x_2, \dots, x_n), \quad (10)$$

and let  $\psi(x)$  be the CONVEX HULL of

$$y_1 = \frac{1}{2}(1 + e^x) \quad (11)$$

$$y_2 = \frac{1 + e^x}{1 + e^{x/2}}. \quad (12)$$

Then

$$\mu = \psi(0) = 0.978012\dots \quad (13)$$

see also CONVEX HULL

**Sharing Problem**

A problem also known as the POINTS PROBLEM or UNFINISHED GAME. Consider a tournament involving  $k$  players playing the same game repetitively. Each game has a single winner, and denote the number of games won by player  $i$  at some juncture  $w_i$ . The games are independent, and the probability of the  $i$ th player winning a game is  $p_i$ . The tournament is specified to continue until one player has won  $n$  games. If the tournament is discontinued before any player has won  $n$  games so that  $w_i < n$  for  $i = 1, \dots, k$ , how should the prize money be shared in order to distribute it proportionally to the players' chances of winning?

For player  $i$ , call the number of games left to win  $r_i \equiv n - w_i > 0$  the "quota." For two players, let  $p \equiv p_1$  and  $q \equiv p_2 = 1 - p$  be the probabilities of winning a single game, and  $a \equiv r_1 = n - w_1$  and  $b \equiv r_2 = n - w_2$  be the number of games needed for each player to win the tournament. Then the stakes should be divided in the ratio  $m : n$ , where

$$m = p^a \left[ 1 + \frac{a}{1}q + \frac{a(a+1)}{2!}q^2 + \dots + \frac{a(a+1) \cdots (a+b-2)}{(b-1)!}q^{b-1} \right] \quad (1)$$

$$n = q^b \left[ 1 + \frac{b}{1}p + \frac{b(b+1)}{2!}p^2 + \dots + \frac{b(b+1) \cdots (b+a-2)}{(a-1)!}p^{a-1} \right] \quad (2)$$

(Kraitchik 1942).

If  $i$  players have equal probability of winning ("cell probability"), then the chance of player  $i$  winning for quotas  $r_1, \dots, r_k$  is

$$W_i = D_1^{k-1}(r_1, \dots, r_{i-1}, r_{i+1}, \dots, r_k; r_i), \quad (3)$$

where  $D$  is the DIRICHLET INTEGRAL of type 2D. Similarly, the chance of player  $i$  losing is

$$L_i = C_1^{k-1}(r_1, \dots, r_{i-1}, r_{i+1}, \dots, r_k; r_i), \quad (4)$$

where  $C$  is the DIRICHLET INTEGRAL of type 2C. If the cell quotas are not equal, the general Dirichlet integral  $D_a$  must be used, where

$$a_i = \frac{p_i}{1 - \sum_{i=1}^{k-1} p_i}. \quad (5)$$

If  $r_i = r$  and  $a_i = 1$ , then  $W_i$  and  $L_i$  reduce to  $1/k$  as they must. Let  $P(r_1, \dots, r_k)$  be the joint probability that the players would be RANKED in the order of the  $r_i$ s in the argument list if the contest were completed. For  $k = 3$ ,

$$P(r_1, r_2, r_3) = CD_1^{(1,1)}(r_1, r_2, r_3). \quad (6)$$

For  $k = 4$  with quota vector  $\mathbf{r} = (r_1, r_2, r_3, r_4)$  and  $\Delta = p_2 + p_3 + p_4$ ,

$$P(\mathbf{r}) = \sum_{i=0}^{r_3-1} \sum_{j=0}^{r_4-1} \binom{r_2-1+i+j}{r_2-1, i, j} \left(\frac{p_2}{\Delta}\right)^{r_2} \left(\frac{p_3}{\Delta}\right)^i \left(\frac{p_4}{\Delta}\right)^j \times C_{p_1/\Delta}^{(1)}(r_1, r_2+i+j) D_{p_4/p_3}^{(1)}(r_4-j, r_3-i). \quad (7)$$

An expression for  $k = 5$  is given by Sobel and Frankowski (1994, p. 838).

see also DIRICHLET INTEGRALS

**Sharkovsky's Theorem**

see ŠARKOVSKII'S THEOREM

**Sharpe's Differential Equation**

A generalization of the BESSEL DIFFERENTIAL EQUATION for functions of order 0, given by

$$zy'' + y' + (z + A)y = 0.$$

Solutions are

$$y = e^{\pm iz} {}_1F_1\left(\frac{1}{2} \mp \frac{1}{2}iA; 1; \mp 2iz\right),$$

where  ${}_1F_1(a; b; x)$  is a CONFLUENT HYPERGEOMETRIC FUNCTION.

see also BESSEL DIFFERENTIAL EQUATION, CONFLUENT HYPERGEOMETRIC FUNCTION

**Sharpe Ratio**

A risk-adjusted financial measure developed by Nobel Laureate William Sharpe. It uses a fund's standard deviation and excess return to determine the reward per unit of risk. The higher a fund's Sharpe ratio, the better the fund's "risk-adjusted" performance.

see also ALPHA, BETA

**Sheaf (Geometry)**

The set of all PLANES through a LINE.

Iyanaga, S. and Kawada, Y. (Eds.). "Sheaves." §377 in *Encyclopedic Dictionary of Mathematics*. Cambridge, MA: MIT Press, p. 1171–1174, 1980.

## Shear

A transformation in which all points along a given LINE  $L$  remain fixed while other points are shifted parallel to  $L$  by a distance proportional to their PERPENDICULAR distance from  $L$ . Shearing a plane figure does not change its AREA. The shear can also be generalized to 3-D, in which PLANES are translated instead of lines.

## Shear Matrix

The shear matrix  $e_{ij}^s$  is obtained from the IDENTITY MATRIX by inserting  $s$  at  $(i, j)$ , e.g.,

$$e_{12}^s = \begin{bmatrix} 1 & s & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

see also ELEMENTARY MATRIX

## Sheppard's Problem

Measurements of a centered convex body in Euclidean  $n$ -space (for  $n \geq 3$ ) show that its brightness function (the volume of each projection) is smaller than that of another such body. Is it true that its VOLUME is also smaller? C. M. Petty and R. Schneider showed in 1967 that the answer is yes if the body with the larger brightness function is a projection body, but no in general for every  $n$ .

## References

Gardner, R. J. "Geometric Tomography." *Not. Amer. Math. Soc.* **42**, 422-429, 1995.

## Sheppard's Correction

A correction which must be applied to the MOMENTS computed from NORMALLY DISTRIBUTED data which have been binned. The corrected versions of the second, third, and fourth moments are

$$\mu_2 = \mu_2^{(0)} - \frac{1}{12}c^2 \quad (1)$$

$$\mu_3 = \mu_3^{(0)} \quad (2)$$

$$\mu_4 = \mu_4^{(0)} - \frac{1}{2}\mu_2^{(0)} + \frac{7}{240}c^2, \quad (3)$$

where  $c$  is the CLASS INTERVAL. If  $\kappa'_r$  is the  $r$ th CUMULANT of an ungrouped distribution and  $\kappa_r$  the  $r$ th CUMULANT of the grouped distribution with CLASS INTERVAL  $c$ , the corrected cumulants (under rather restrictive conditions) are

$$\kappa'_r = \begin{cases} \kappa_r & \text{for } r \text{ odd} \\ \kappa_r - \frac{B_r}{r}c^r & \text{for } r \text{ even,} \end{cases} \quad (4)$$

where  $B_r$  is the  $r$ th BERNOULLI NUMBER, giving

$$\kappa'_1 = \kappa_1 \quad (5)$$

$$\kappa'_2 = \kappa_2 - \frac{1}{12}c^2 \quad (6)$$

$$\kappa'_3 = \kappa_3 \quad (7)$$

$$\kappa'_4 = \kappa_4 + \frac{1}{120}c^4 \quad (8)$$

$$\kappa'_5 = \kappa_5 \quad (9)$$

$$\kappa'_6 = \kappa_6 - \frac{1}{252}c^6. \quad (10)$$

For a proof, see Kendall *et al.* (1987).

## Sherman-Morrison Formula

A formula which allows the new MATRIX to be computed for a small change to a MATRIX  $A$ . If the change can be written in the form

$$u \otimes v$$

for two vectors  $u$  and  $v$ , then the Sherman-Morrison formula is

$$(A + u \otimes v)^{-1} = A^{-1} - \frac{(A^{-1}u) \otimes (v \cdot A^{-1})}{1 + \lambda},$$

where

$$\lambda = v \cdot A^{-1}u.$$

see also WOODBURY FORMULA

### Shuffle

The randomization of a deck of CARDS by repeated interleaving. More generally, a shuffle is a rearrangement of the elements in an ordered list. Shuffling by exactly interleaving two halves of a deck is called a RIFFLE SHUFFLE. Normal shuffling leaves gaps of different lengths between the two layers of cards and so randomizes the order of the cards.

A deck of 52 CARDS must be shuffled seven times for it to be randomized (Aldous and Diaconis 1986, Bayer and Diaconis 1992). This is intermediate between too few shuffles and the decreasing effectiveness of many shuffles. One of Bayer and Diaconis's randomness CRITERIA, however, gives  $3 \lg k/2$  shuffles for a  $k$ -card deck, yielding 11–12 shuffles for 52 CARDS. Keller (1995) shows that roughly  $\ln k$  shuffles are needed just to randomize the bottom card.

### Siegel's Paradox

If a fixed FRACTION  $x$  of a given amount of money  $P$  is lost, and then the same FRACTION  $x$  of the remaining amount is gained, the result is less than the original and equal to the final amount if a FRACTION  $x$  is first gained, then lost. This can easily be seen from the fact that

$$[P(1-x)](1+x) = P(1-x^2) < P$$

$$[P(1+x)](1-x) = P(1-x^2) < P.$$

### Siegel's Theorem

An ELLIPTIC CURVE can have only a finite number of points with INTEGER coordinates.

see also ELLIPTIC CURVE

## Sierpiński Carpet

A FRACTAL which is constructed analogously to the SIERPIŃSKI SIEVE, but using squares instead of triangles. Let  $N_n$  be the number of black boxes,  $L_n$  the length of a side of a white box, and  $A_n$  the fractional AREA of black boxes after the  $n$ th iteration. Then

$$N_n = 8^n \quad (1)$$

$$L_n = \left(\frac{1}{3}\right)^n = 3^{-n} \quad (2)$$

$$A_n = L_n^2 N_n = \left(\frac{8}{9}\right)^n. \quad (3)$$

The CAPACITY DIMENSION is therefore

$$\begin{aligned} d_{\text{cap}} &= -\lim_{n \rightarrow \infty} \frac{\ln N_n}{\ln L_n} = -\lim_{n \rightarrow \infty} \frac{\ln(8^n)}{\ln(3^{-n})} = \frac{\ln 8}{\ln 3} \\ &= \frac{3 \ln 2}{\ln 3} = 1.892789261 \dots \end{aligned} \quad (4)$$

## Sierpiński's Composite Number Theorem

There exist infinitely many ODD INTEGERS  $k$  such that  $k \cdot 2^n + 1$  is COMPOSITE for every  $n \geq 1$ . Numbers  $k$  with this property are called SIERPIŃSKI NUMBERS OF THE SECOND KIND, and analogous numbers with the plus sign replaced by a minus are called RIESEL NUMBERS. It is conjectured that the smallest SIERPIŃSKI NUMBER OF THE SECOND KIND is  $k = 78,557$  and the smallest RIESEL NUMBER is  $k = 509,203$ .

## Sierpiński Constant

Let  $r_k(n)$  denote the number of representations of  $n$  by  $k$  squares, then the SUMMATORY FUNCTION of  $r_2(k)/k$  has the ASYMPTOTIC expansion

$$\sum_{k=1}^n \frac{r_2(k)}{k} = K + \pi \ln n + \mathcal{O}(n^{-1/2}),$$

where  $K = 2.5849817596$  is the Sierpiński constant. The above plot shows

$$\left[ \sum_{k=1}^n \frac{r_2(k)}{k} \right] - \pi \ln n,$$

with the value of  $K$  indicated as the solid horizontal line.  
 see also  $r_k(n)$

## Sierpiński Curve

There are several FRACTAL curves associated with Sierpiński. The above curve is one example, and the SIERPIŃSKI ARROWHEAD CURVE is another. The limit of the curve illustrated above has AREA

$$A = \frac{5}{12}.$$

The AREA for a related curve illustrated by Cundy and Rollett (1989) is

$$A = \frac{1}{3}(7 - 4\sqrt{2}).$$

### Sierpiński-Menger Sponge

see Menger SPONGE

### Sierpiński Number of the First Kind

Numbers of the form  $S_n \equiv n^n + 1$ . The first few are 2, 5, 28, 257, 3126, 46657, 823544, 16777217, ... (Sloane's A014566). Sierpiński proved that if  $S_n$  is PRIME with  $n \geq 2$ , then  $S_n = F_{m+2^m}$ , where  $F_m$  is a FERMAT NUMBER with  $m \geq 0$ . The first few such numbers are  $F_1 = 5$ ,  $F_3 = 257$ ,  $F_6$ ,  $F_{11}$ ,  $F_{20}$ , and  $F_{37}$ . Of these, 5 and 257 are PRIME, and the first unknown case is  $F_{37} > 10^{3 \times 10^{10}}$ .

### Sierpiński Number of the Second Kind

A number  $k$  satisfying SIERPIŃSKI'S COMPOSITE NUMBER THEOREM, i.e., such that  $k \cdot 2^n + 1$  is COMPOSITE for every  $n \geq 1$ . The smallest known is  $k = 78,557$ , but there remain 35 smaller candidates (the smallest of which is 4847) which are known to generate only composite numbers for  $n \leq 18,000$  or more (Ribenboim 1996, p. 358).

Let  $a(k)$  be smallest  $n$  for which  $(2k - 1) \cdot 2^n + 1$  is PRIME, then the first few values are 0, 1, 1, 2, 1, 1, 2, 1, 3, 6, 1, 1, 2, 2, 1, 8, 1, 1, 2, 1, 1, 2, 2, 583, ... (Sloane's A046067). The second smallest  $n$  are given by 1, 2, 3, 4, 2, 3, 8, 2, 15, 10, 4, 9, 4, 4, 3, 60, 6, 3, 4, 2, 11, 6, 9, 1483, ... (Sloane's A046068). Quite large  $n$  can be required to the first prime even for small  $k$ . For example, the smallest prime of the form  $383 \cdot 2^n + 1$  is  $383 \cdot 2^{6393} + 1$ . There are an infinite number of Sierpiński numbers which are PRIME.

The smallest odd  $k$  such that  $k + 2^n$  is COMPOSITE for all  $n < k$  are 773, 2131, 2491, 4471, 5101, ...

### Sierpiński Sieve

A FRACTAL described by Sierpiński in 1915. It is also called the SIERPIŃSKI GASKET or SIERPIŃSKI TRIANGLE. The curve can be written as a LINDENMAYER SYSTEM with initial string "FXF--FF--FF", STRING REWRITING rules "F"  $\rightarrow$  "FF", "X"  $\rightarrow$  "--FXF++FXF++FXF--", and angle  $60^\circ$ .

Let  $N_n$  be the number of black triangles after iteration  $n$ ,  $L_n$  the length of a side of a triangle, and  $A_n$  the fractional AREA which is black after the  $n$ th iteration. Then

$$N_n = 3^n \quad (1)$$

$$L_n = \left(\frac{1}{2}\right)^n = 2^{-n} \quad (2)$$

$$A_n = L_n^2 N_n = \left(\frac{3}{4}\right)^n. \quad (3)$$

The CAPACITY DIMENSION is therefore

$$d_{\text{cap}} = - \lim_{n \rightarrow \infty} \frac{\ln N_n}{\ln L_n} = - \lim_{n \rightarrow \infty} \frac{\ln(3^n)}{\ln(2^{-n})} = \frac{\ln 3}{\ln 2} = 1.584962501 \dots \quad (4)$$

In PASCAL'S TRIANGLE, coloring all ODD numbers black and EVEN numbers white produces a Sierpiński sieve.

### Sieve

A process of successively crossing out members of a list according to a set of rules such that only some remain. The best known sieve is the ERATOSTHENES SIEVE for generating PRIME NUMBERS. In fact, numbers generated by sieves seem to share a surprisingly large number of properties with the PRIME NUMBERS.

An ALGORITHM for making tables of PRIMES. Sequentially write down the INTEGERS from 2 to the highest number  $n$  you wish to include in the table. Cross out all numbers  $> 2$  which are divisible by 2 (every second number). Find the smallest remaining number  $> 2$ . It is 3. So cross out all numbers  $> 3$  which are divisible by 3 (every third number). Find the smallest remaining number  $> 3$ . It is 5. So cross out all numbers  $> 5$  which are divisible by 5 (every fifth number).

Continue until you have crossed out all numbers divisible by  $\lfloor \sqrt{n} \rfloor$ , where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. The numbers remaining are PRIME. This procedure is illustrated in the above diagram which sieves up to 50, and therefore crosses out PRIMES up to  $\lfloor \sqrt{50} \rfloor = 7$ . If the procedure is then continued up to  $n$ , then the number of cross-outs gives the number of distinct PRIME factors of each number.

## Sievert's Surface

A special case of ENNEPER'S SURFACES which can be given parametrically by

$$x = r \cos \phi \quad (1)$$

$$y = r \sin \phi \quad (2)$$

$$z = \frac{\ln[\tan(\frac{1}{2}v)] + a(C+1) \cos v}{\sqrt{C}}, \quad (3)$$

where

$$\phi \equiv -\frac{u}{\sqrt{C+1}} + \tan^{-1}(\tan u \sqrt{C+1}) \quad (4)$$

$$a \equiv \frac{2}{C+1 - C \sin^2 v \cos^2 u} \quad (5)$$

$$r \equiv \frac{a \sqrt{(C+1)(1 + C \sin^2 u)} \sin v}{\sqrt{C}}, \quad (6)$$

with  $|u| < \pi/2$  and  $0 < v < \pi$  (Reckziegel 1986).

see also ENNEPER'S SURFACES, KUEN SURFACE, REMBS' SURFACES

## Sifting Property

The property

$$\int f(y) \delta(x-y) dy = f(x)$$

obeyed by the DELTA FUNCTION  $\delta(x)$ .

see also DELTA FUNCTION

## Sigma Algebra

Let  $X$  be a SET. Then a  $\sigma$ -algebra  $F$  is a nonempty collection of SUBSETS of  $X$  such that the following hold:

1. The EMPTY SET is in  $F$ .
2. If  $A$  is in  $F$ , then so is the complement of  $A$ .
3. If  $A_n$  is a SEQUENCE of elements of  $F$ , then the UNION of the  $A_n$ s is in  $F$ .

If  $S$  is any collection of subsets of  $X$ , then we can always find a  $\sigma$ -algebra containing  $S$ , namely the POWER SET of  $X$ . By taking the INTERSECTION of all  $\sigma$ -algebras containing  $S$ , we obtain the smallest such  $\sigma$ -algebra. We call the smallest  $\sigma$ -algebra containing  $S$  the  $\sigma$ -algebra generated by  $S$ .

**Signalizer Functor Theorem**

$$\Theta(G; A) = \langle \theta(a) : a \in A - 1 \rangle$$

is an  $A$ -invariant solvable  $p'$ -subgroup of  $G$ .

**Signature (Knot)**

The signature  $s(K)$  of a **KNOT**  $K$  can be defined using the **SKEIN RELATIONSHIP**

$$s(\text{unknot}) = 0$$

$$s(K_+) - s(K_-) \in \{0, 2\},$$

and

$$4|s(K) \leftrightarrow \nabla(K)(2i) > 0,$$

where  $\nabla(K)$  is the **ALEXANDER-CONWAY POLYNOMIAL** and  $\nabla(K)(2i)$  is an **ODD NUMBER**.

Many **UNKNOTTING NUMBERS** can be determined using a knot's signature.

see also **SKEIN RELATIONSHIP**, **UNKNOTTING NUMBER**

**Signature (Quadratic Form)**

The signature of the **QUADRATIC FORM**

$$Q = y_1^2 + y_2^2 + \dots + y_p^2 - y_{p+1}^2 - y_{p+2}^2 - \dots - y_r^2$$

is the number  $s$  of **POSITIVE** squared terms in the reduced form. (The signature is sometimes defined as  $2s - r$ .)

see also  $p$ -**SIGNATURE**, **RANK (QUADRATIC FORM)**, **SYLVESTER'S INERTIA LAW**, **SYLVESTER'S SIGNATURE**

**References**

- Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products*, 5th ed. San Diego, CA: Academic Press, p. 1105, 1979.

**Signature (Recurrence Relation)**

Let a sequence be defined by

$$A_{-1} = s$$

$$A_0 = 3$$

$$A_1 = r$$

$$A_n = rA_{n-1} - sA_{n-2} + A_{n-3}.$$

Also define the associated **POLYNOMIAL**

$$f(x) = x^3 - rx^2 + sx + 1,$$

and let  $\Delta$  be its discriminant. The **PERRIN SEQUENCE** is a special case corresponding to  $A_n(0, -1)$ . The signature mod  $m$  of an **INTEGER**  $n$  with respect to the sequence  $A_k(r, s)$  is then defined as the 6-tuple  $(A_{-n-1}, A_{-n}, A_{-n+1}, A_{n-1}, A_n, A_{n+1}) \pmod{m}$ .

1. An **INTEGER**  $n$  has an **S-signature** if its signature  $\pmod{n}$  is  $(A_{-2}, A_{-1}, A_0, A_1, A_2)$ .
2. An **INTEGER**  $n$  has a **Q-signature** if its signature  $\pmod{n}$  is **CONGRUENT** to  $(A, s, B, r, C)$  where, for some **INTEGER**  $a$  with  $f(a) \equiv 0 \pmod{n}$ ,  $A \equiv a^{-2} + 2a$ ,  $B \equiv -ra^2 + (r^2 - s)a$ , and  $C \equiv a^2 + 2a^{-1}$ .
3. An **INTEGER**  $n$  has an **I-signature** if its signature  $\pmod{n}$  is **CONGRUENT** to  $(r, s, D', D, r, s)$ , where  $D' + D \equiv rs - 3$  and  $(D' - D)^2 \equiv \Delta$ .

see also **PERRIN PSEUDOPRIME**

- Grantham, J. “Frobenius Pseudoprimes.” <http://www.clark.net/pub/grantham/pseudo/pseudo.ps>

**Signature Sequence**

Let  $\theta$  be an **IRRATIONAL NUMBER**, define  $S(\theta) = \{c + d\theta : c, d \in \mathbb{N}\}$ , and let  $c_n(\theta) + d_n\theta(\theta)$  be the sequence obtained by arranging the elements of  $S(\theta)$  in increasing order. A sequence  $x$  is said to be a signature sequence if there **EXISTS** a **POSITIVE IRRATIONAL NUMBER**  $\theta$  such that  $x = \{c_n(\theta)\}$ , and  $x$  is called the signature of  $\theta$ .

The signature of an **IRRATIONAL NUMBER** is a **FRACTAL SEQUENCE**. Also, if  $x$  is a signature sequence, then the **LOWER-TRIMMED SUBSEQUENCE** is  $V(x) = x$ .

**References**

- Kimberling, C. “Fractal Sequences and Interspersions.” *Ars Combin.* **45**, 157–168, 1997.

**Signed Deviation**

The signed deviation is defined by

$$\Delta u_i \equiv (u_i - \bar{u}),$$

so the average deviation is

$$\overline{\Delta u} = \overline{u_i - \bar{u}} = \bar{u}_i - \bar{u} = 0.$$

see also **ABSOLUTE DEVIATION**, **DEVIATION**, **DISPER-SION (STATISTICS)**, **MEAN DEVIATION**, **QUARTILE DEVIATION**, **STANDARD DEVIATION**, **VARIANCE**

### Significance

Let  $\delta \equiv z \leq z_{\text{observed}}$ . A value  $0 \leq \alpha \leq 1$  such that  $P(\delta) \leq \alpha$  is considered "significant" (i.e., is not simply due to chance) is known as an ALPHA VALUE. The PROBABILITY that a variate would assume a value greater than or equal to the observed value strictly by chance,  $P(\delta)$ , is known as a P-VALUE.

Depending on the type of data and conventional practices of a given field of study, a variety of different alpha values may be used. One commonly used terminology takes  $P(\delta) \geq 5\%$  as "not significant,"  $1\% < P(\delta) < 5\%$ , as "significant" (sometimes denoted \*), and  $P(\delta) < 1\%$  as "highly significant" (sometimes denoted \*\*). Some authors use the term "almost significant" to refer to  $5\% < P(\delta) < 10\%$ , although this practice is not recommended.

see also ALPHA VALUE, CONFIDENCE INTERVAL, P-VALUE, PROBABLE ERROR, SIGNIFICANCE TEST, STATISTICAL TEST

### Significance Test

A test for determining the probability that a given result could not have occurred by chance (its SIGNIFICANCE).

### Significant Digits

When a number is expressed in SCIENTIFIC NOTATION, the number of significant figures is the number of DIGITS needed to express the number to within the uncertainty of measurement. For example, if a quantity had been measured to be  $1.234 \pm 0.002$ , four figures would be significant. No more figures should be given than are allowed by the uncertainty. For example, a quantity written as  $1.234 \pm 0.1$  is incorrect; it should really be written as  $1.2 \pm 0.1$ .

The number of significant figures of a MULTIPLICATION or DIVISION of two or more quantities is equal to the smallest number of significant figures for the quantities involved. For ADDITION or MULTIPLICATION, the number of significant figures is determined with the smallest significant figure of all the quantities involved. For example, the sum  $10.234 + 5.2 + 100.3234$  is 115.7574, but should be written 115.8 (with rounding), since the quantity 5.2 is significant only to  $\pm 0.1$ .

### Silver Mean

see SILVER RATIO

### Silver Ratio

The quantity defined by the CONTINUED FRACTION

$$\delta_S \equiv [2, 2, 2, \dots] = 2 + \frac{1}{2 + \frac{1}{2 + \frac{1}{2 + \dots}}}$$

It follows that

$$(\delta_S - 1)^2 = 2,$$

so

$$\delta_S = \sqrt{2} + 1 = 2.41421\dots$$

see also GOLDEN RATIO, GOLDEN RATIO CONJUGATE

### Silverman Constant

$$\sum_{n=1}^{\infty} \frac{1}{\phi(n)\sigma(n)} = \prod_{p \text{ prime}} \left( 1 + \sum_{k=1}^{\infty} \frac{1}{p^{2k} - p^{k-1}} \right) = 1.786576459\dots,$$

where  $\phi(n)$  is the TOTIENT FUNCTION and  $\sigma(n)$  is the DIVISOR FUNCTION.

### Silverman's Sequence

Let  $f(1) = 1$ , and let  $f(n)$  be the number of occurrences of  $n$  in a nondecreasing sequence of INTEGERS. Then the first few values of  $f(n)$  are 1, 2, 2, 3, 3, 4, 4, 4, 5, 5, 5, ... (Sloane's A001462). The asymptotic value of the  $n$ th term is  $\phi^{2-\phi}n^{\phi-1}$ , where  $\phi$  is the GOLDEN RATIO.

### Similar

Two figures are said to be similar when all corresponding ANGLES are equal. Two figures are DIRECTLY SIMILAR when all corresponding ANGLES are equal and described in the same rotational sense. This relationship is written  $A \sim B$ . (The symbol  $\sim$  is also used to mean "is the same order of magnitude as" and "is ASYMPTOTIC to.") Two figures are INVERSELY SIMILAR when all corresponding ANGLES are equal and described in the opposite rotational sense.

### Similarity Axis

see D'ALEMBERT'S THEOREM

### Similarity Dimension

To multiply the size of a  $d$ -D object by a factor  $a$ ,  $c \equiv a^d$  copies are required, and the quantity

$$d = \frac{\ln c}{\ln a}$$

is called the similarity dimension.

### Similarity Point

External (or positive) and internal (or negative) similarity points of two CIRCLES with centers  $C$  and  $C'$  and RADII  $r$  and  $r'$  are the points  $E$  and  $I$  on the lines  $CC'$  such that

$$\frac{CE}{C'E} = \frac{r}{r'},$$

or

$$\frac{CI}{C'I} = -\frac{r}{r'}.$$

### Similarity Transformation

An ANGLE-preserving transformation. A similarity transformation has a transformation MATRIX  $A'$  of the form

$$A' \equiv BAB^{-1}.$$

If  $A$  is an ANTISYMMETRIC MATRIX ( $a_{ij} = -a_{ji}$ ) and  $B$  is an ORTHOGONAL MATRIX, then

$$\begin{aligned} (bab^{-1})_{ij} &= b_{ik}a_{kl}b_{lj}^{-1} = -b_{ik}a_{lk}b_{lj}^{-1} = -b_{ki}^{\dagger}a_{lk}(b^{\dagger})_{jl}^{-1} \\ &= -b_{ki}^{-1}a_{lk}b_{lj} = b_{jl}a_{lk}b_{ki}^{-1} = -(bab^{-1})_{ji}. \end{aligned}$$

Similarity transformations and the concept of SELF-SIMILARITY are important foundations of FRACTALS and ITERATED FUNCTION SYSTEMS.

see also CONFORMAL TRANSFORMATION

### Similitude Center

Also called a SELF-HOMOLOGOUS POINT. If two SIMILAR figures lie in the plane but do not have parallel sides (they are not HOMOTHETIC), there exists a center of similitude which occupies the same homologous position with respect to the two figures. The LOCUS of similitude centers of two nonconcentric circles is another circle having the line joining the two homothetic centers as its DIAMETER.

There are a number of interesting theorems regarding three CIRCLES (Johnson 1929, pp. 151–152).

1. The external similitude centers of three circles are COLLINEAR.
2. Any two internal similitude centers are COLLINEAR with the third external one.
3. If the center of each circle is connected with the internal similitude center of the other three [sic], the connectors are CONCURRENT.
4. If one center is connected with the internal similitude center of the other two, the others with the corresponding external centers, the connectors are CONCURRENT.

### Similitude Ratio

Two figures are HOMOTHETIC if they are related by a DILATION (a dilation is also known as a HOMOTHECY). This means that the connectors of corresponding points are CONCURRENT at a point which divides each connector in the same ratio  $k$ , known as the similitude ratio.

**Simple Continued Fraction**

A CONTINUED FRACTION

$$\sigma = b_0 + \frac{a_1}{b_1 + \frac{a_2}{b_2 + \frac{a_3}{b_3 + \dots}}} \quad (1)$$

in which the  $b_i$ s are all unity, leaving a continued fraction of the form

$$\sigma = a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \dots}}} \quad (2)$$

A simple continued fraction can be written in a compact abbreviated NOTATION as

$$\sigma = [a_0, a_1, a_2, a_3, \dots]. \quad (3)$$

Bach and Shallit (1996) show how to compute the JACOBI SYMBOL in terms of the simple continued fraction of a RATIONAL NUMBER  $a/b$ .

**Simple Curve**

A curve is simple closed if it does not cross itself.

see also JORDAN CURVE

**Simple Graph**

A GRAPH for which at most one EDGE connects any two nodes.

see also ADJACENCY MATRIX, EDGE (GRAPH)

**Simple Group**

A simple group is a GROUP whose NORMAL SUBGROUPS (INVARIANT SUBGROUPS) are ORDER one or the whole of the original GROUP. Simple groups include ALTERNATING GROUPS, CYCLIC GROUPS, LIE-TYPE GROUPS (five varieties), and SPORADIC GROUPS (26 varieties, including the MONSTER GROUP). The CLASSIFICATION THEOREM of finite simple groups states that such groups can be classified completely into the three types:

1. CYCLIC GROUPS of PRIME ORDER,
2. ALTERNATING GROUPS of degree at least five
3. LIE-TYPE CHEVALLEY GROUPS,

4. LIE-TYPE (TWISTED CHEVALLEY GROUPS or the TITS GROUP), and

5. SPORADIC GROUPS.

BURNSIDE'S CONJECTURE states that every non-ABELIAN SIMPLE GROUP has EVEN ORDER.

see also ALTERNATING GROUP, BURNSIDE'S CONJECTURE, CHEVALLEY GROUPS, CLASSIFICATION THEOREM, CYCLIC GROUP, FEIT-THOMPSON THEOREM, FINITE GROUP, GROUP, INVARIANT SUBGROUP, LIE-TYPE GROUP, MONSTER GROUP, SCHUR MULTIPLIER, SPORADIC GROUP, TITS GROUP, TWISTED CHEVALLEY GROUPS

**Simple Harmonic Motion**

Simple harmonic motion refers to the periodic sinusoidal oscillation of an object or quantity. Simple harmonic motion is executed by any quantity obeying the DIFFERENTIAL EQUATION

$$\ddot{x} + \omega_0^2 x = 0, \quad (1)$$

where  $\ddot{x}$  denotes the second DERIVATIVE of  $x$  with respect to  $t$ , and  $\omega_0$  is the angular frequency of oscillation. This ORDINARY DIFFERENTIAL EQUATION has an irregular SINGULARITY at  $\infty$ . The general solution is

$$x = A \sin(\omega_0 t) + B \cos(\omega_0 t) \quad (2)$$

$$= C \cos(\omega_0 t + \phi), \quad (3)$$

where the two constants  $A$  and  $B$  (or  $C$  and  $\phi$ ) are determined from the initial conditions.

Many physical systems undergoing small displacements, including any objects obeying Hooke's law, exhibit simple harmonic motion. This equation arises, for example, in the analysis of the flow of current in an electronic CL circuit (which contains a capacitor and an inductor). If a damping force such as Friction is present, an additional term  $\beta\dot{x}$  must be added to the DIFFERENTIAL EQUATION and motion dies out over time.

Adding a damping force proportional to  $\dot{x}$ , the first derivative of  $x$  with respect to time, the equation of motion for *damped* simple harmonic motion is

$$\ddot{x} + \beta\dot{x} + \omega_0^2 x = 0, \quad (4)$$

where  $\beta$  is the damping constant. This equation arises, for example, in the analysis of the flow of current in an electronic CLR circuit, (which contains a capacitor, an inductor, and a resistor). This ORDINARY DIFFERENTIAL EQUATION can be solved by looking for trial solutions of the form  $x = e^{rt}$ . Plugging this into (4) gives

$$(r^2 + \beta r + \omega_0^2)e^{rt} = 0 \quad (5)$$

$$r^2 + \beta r + \omega_0^2 = 0. \quad (6)$$

This is a QUADRATIC EQUATION with solutions

$$r = \frac{1}{2}(-\beta \pm \sqrt{\beta^2 - 4\omega_0^2}). \quad (7)$$

There are therefore three solution regimes depending on the SIGN of the quantity inside the SQUARE ROOT,

$$\alpha \equiv \beta^2 - 4\omega_0^2. \quad (8)$$

The three regimes are

1.  $\alpha > 0$  is POSITIVE: overdamped,
2.  $\alpha = 0$  is ZERO: critically damped,
3.  $\alpha < 0$  is NEGATIVE: underdamped.

If a periodic (sinusoidal) forcing term is added at angular frequency  $\omega$ , the same three solution regimes are again obtained. Surprisingly, the resulting motion is still periodic (after an initial transient response, corresponding to the solution to the unforced case, has died out), but it has an amplitude different from the forcing amplitude.

The "particular" solution  $x_p(t)$  to the forced second-order nonhomogeneous ORDINARY DIFFERENTIAL EQUATION

$$\ddot{x} + p(t)\dot{x} + q(t)x = A \cos(\omega t) \quad (9)$$

due to forcing is given by the equation

$$x_p(t) = -x_1(t) \int \frac{x_2(t)g(t)}{W(t)} dt + x_2(t) \int \frac{x_1(t)g(t)}{W(t)} dt, \quad (10)$$

where  $x_1$  and  $x_2$  are the homogeneous solutions to the unforced equation

$$\ddot{x} + p(t)\dot{x} + q(t)x = 0 \quad (11)$$

and  $W(t)$  is the WRONSKIAN of these two functions. Once the sinusoidal case of forcing is solved, it can be generalized to *any* periodic function by expressing the periodic function in a FOURIER SERIES.

Critical damping is a special case of damped simple harmonic motion in which

$$\alpha \equiv \beta^2 - 4\omega_0^2 = 0, \quad (12)$$

so

$$\beta = 2\omega_0. \quad (13)$$

The above plot shows an underdamped simple harmonic oscillator with  $\omega = 0.3$ ,  $\beta = 0.15$ . The solid curve is for  $(A, B) = (1, 0)$ , the dot-dashed for  $(0, 1)$ , and the dotted for  $(1/2, 1/2)$ . In this case,  $\alpha = 0$  so the solutions of the form  $x = e^{rt}$  satisfy

$$r_{\pm} = \frac{1}{2}(-\beta) = -\frac{1}{2}\beta = -\omega_0. \quad (14)$$

One of the solutions is therefore

$$x_1 = e^{-\omega_0 t}. \quad (15)$$

In order to find the other linearly independent solution, we can make use of the identity

$$x_2(t) = x_1(t) \int \frac{e^{-\int p(t) dt}}{[x_1(t)]^2} dt. \quad (16)$$

Since we have  $p(t) = 2\omega_0$ ,  $e^{-\int p(t) dt}$  simplifies to  $e^{-2\omega_0 t}$ . Equation (16) therefore becomes

$$x_2(t) = e^{-\omega_0 t} \int \frac{e^{-2\omega_0 t}}{[e^{-\omega_0 t}]^2} dt = e^{-\omega_0 t} \int dt = te^{-\omega_0 t}. \quad (17)$$

The general solution is therefore

$$x = (A + Bt)e^{-\omega_0 t}. \quad (18)$$

In terms of the constants  $A$  and  $B$ , the initial values are

$$x(0) = A \quad (19)$$

$$x'(0) = B - A\omega_0, \quad (20)$$

so

$$A = x(0) \quad (21)$$

$$B = x'(0) + \omega_0 x(0). \quad (22)$$

For sinusoidally forced simple harmonic motion with critical damping, the equation of motion is

$$\ddot{x} + 2\omega_0\dot{x} + \omega_0^2 x = A \cos(\omega t), \quad (23)$$

and the WRONSKIAN is

$$\begin{aligned} W(t) &\equiv x_1\dot{x}_2 - \dot{x}_1x_2 \\ &= e^{-\omega_0 t}(e^{-\omega_0 t} - \omega_0 te^{-\omega_0 t}) + \omega_0 e^{-\omega_0 t}te^{-\omega_0 t} \\ &= e^{-2\omega_0 t}(1 - \omega_0 t + \omega_0 t) = e^{-2\omega_0 t}. \end{aligned} \quad (24)$$

Plugging this into the equation for the particular solution gives

$$\begin{aligned}
 x_p(t) &= -e^{-\omega_0 t} \int \frac{te^{-\omega_0 t} A \cos(\omega t)}{e^{-2\omega_0 t}} dt \\
 &\quad + te^{-\omega_0 t} \int \frac{e^{-\omega_0 t} A \cos(\omega t)}{e^{-2\omega_0 t}} dt \\
 &= Ae^{-\omega_0 t} \left[ - \int te^{\omega_0 t} \cos(\omega t) dt + t \int e^{\omega_0 t} \cos(\omega t) dt \right] \\
 &= Ae^{-\omega_0 t} \left\{ - \frac{e^{\omega_0 t}}{(\omega^2 + \omega_0^2)^2} [(\omega^2 + t\omega^2\omega_0 - \omega_0^2 + t\omega_0^3) \right. \\
 &\quad \times \cos(\omega t) + \omega(t\omega^2 - 2\omega_0 + t\omega_0^2) \sin(\omega t)] \\
 &\quad \left. + t \frac{e^{\omega_0 t}}{\omega^2 + \omega_0^2} [\omega_0 \cos(\omega t) + \omega \sin(\omega t)] \right\} \\
 &= \frac{A}{(\omega^2 + \omega_0^2)^2} [(\omega_0^2 - \omega^2) \cos(\omega t) + 2\omega\omega_0 \sin(\omega t)].
 \end{aligned} \tag{25}$$

In order to put this in the desired form, note that we want to equate

$$\begin{aligned}
 C \cos \theta + S \sin \theta &= Q \cos(\theta + \delta) \\
 &= Q(\cos \theta \cos \delta - \sin \theta \sin \delta).
 \end{aligned} \tag{26}$$

This means

$$C \equiv Q \cos \delta = \omega_0^2 - \omega^2 \tag{27}$$

$$S \equiv -Q \sin \delta = 2\omega\omega_0, \tag{28}$$

so

$$Q = \sqrt{C^2 + S^2} \tag{29}$$

$$\delta = \tan^{-1} \left( -\frac{S}{C} \right). \tag{30}$$

Plugging in,

$$\begin{aligned}
 Q &= \sqrt{\omega_0^4 - 2\omega_0^2\omega^2 + \omega^4 + 4\omega_0^2\omega^2} \\
 &= \sqrt{\omega_0^4 + 2\omega_0^2\omega^2 + \omega^4} = \omega_0^2 + \omega^2.
 \end{aligned} \tag{31}$$

$$\delta = \tan^{-1} \left( \frac{2\omega\omega_0}{\omega^2 - \omega_0^2} \right). \tag{32}$$

The solution in the requested form is therefore

$$\begin{aligned}
 x_p &= \frac{A}{(\omega^2 + \omega_0^2)^2} (\omega_0^2 + \omega^2) \cos(\omega t + \delta) \\
 &= \frac{A}{\omega^2 + \omega_0^2} \cos(\omega t + \delta),
 \end{aligned} \tag{33}$$

where  $\delta$  is defined by (32).

Overdamped simple harmonic motion occurs when

$$\beta^2 - 4\omega_0^2 > 0, \tag{34}$$

so

$$\alpha \equiv \beta^2 - 4\omega_0^2 > 0. \tag{35}$$

The above plot shows an overdamped simple harmonic oscillator with  $\omega = 0.3$ ,  $\beta = 0.075$ . The solid curve is for  $(A, B) = (1, 0)$ , the dot-dashed for  $(0, 1)$ , and the dotted for  $(1/2, 1/2)$ . The solutions are

$$x_1 = e^{r_- t} \tag{36}$$

$$x_2 = e^{r_+ t}, \tag{37}$$

where

$$r_{\pm} \equiv \frac{1}{2}(-\beta \pm \sqrt{\beta^2 - 4\omega_0^2}). \tag{38}$$

The general solution is therefore

$$x = Ae^{r_- t} + Be^{r_+ t}, \tag{39}$$

where  $A$  and  $B$  are constants. The initial values are

$$x(0) = A + B \tag{40}$$

$$x'(0) = Ar_- + Br_+, \tag{41}$$

so

$$A = x(0) + \frac{r_+ x(0) - x'(0)}{r_- - r_+} \tag{42}$$

$$B = -\frac{r_+ x(0) - x'(0)}{r_- - r_+}. \tag{43}$$

For a cosinusoidally forced overdamped oscillator with forcing function  $g(t) = C \cos(\omega t)$ , the particular solutions are

$$y_1(t) = e^{r_1 t} \tag{44}$$

$$y_2(t) = e^{r_2 t}, \tag{45}$$

where

$$r_1 \equiv \frac{1}{2}(-\beta + \sqrt{\beta^2 - 4\omega_0^2}) \tag{46}$$

$$r_2 \equiv \frac{1}{2}(-\beta - \sqrt{\beta^2 - 4\omega_0^2}). \tag{47}$$

These give the identities

$$r_1 + r_2 = -\beta \quad (48)$$

$$r_1 - r_2 = \sqrt{\beta^2 - 4\omega_0^2} \quad (49)$$

and

$$\begin{aligned} \omega_0^2 &= \frac{1}{4}[\beta - (r_1 - r_2)^2] = \frac{1}{4}[(r_1 + r_2)^2 - (r_1 - r_2)^2] \\ &= \frac{1}{4}[2r_1r_2 + 2r_1r_2] = r_1r_2. \end{aligned} \quad (50)$$

The WRONSKIAN is

$$\begin{aligned} W(t) &\equiv y_1 y_2' - y_1' y_2 = e^{r_1 t} r_2 e^{r_2 t} - r_1 e^{r_1 t} e^{r_2 t} \\ &= (r_2 - r_1) e^{(r_1 + r_2)t}. \end{aligned} \quad (51)$$

The particular solution is

$$y_p = -y_1 v_1 + y_2 v_2, \quad (52)$$

where

$$\begin{aligned} v_1 &\equiv \int \frac{y_2 g(t)}{W(t)} = \frac{C}{r_2 - r_1} \frac{\omega \sin(\omega t) - r_2 \cos(\omega t)}{e^{r_2 t} (r_2^2 + \omega^2)} \quad (53) \\ v_2 &\equiv \int \frac{y_1 g(t)}{W(t)} = \frac{C}{r_2 - r_1} \frac{\omega \sin(\omega t) - r_1 \cos(\omega t)}{e^{r_1 t} (r_2^2 + \omega^2)}. \end{aligned} \quad (54)$$

Therefore,

$$\begin{aligned} y_p &= C \frac{\cos(\omega t)(r_1 r_2 - \omega^2) - \sin(\omega t)\omega(r_1 + r_2)}{(r_1^2 + \omega^2)(r_2^2 + \omega^2)} \\ &= C \frac{(\omega_0^2 - \omega^2) \cos(\omega t) + \beta \omega \sin(\omega t)}{\omega^2 \beta^2 + (\omega^2 - \omega_0^2)} \\ &= \frac{C}{\omega^2 \beta^2 + (\omega^2 - \omega_0^2)^2} \sqrt{(\omega^2 - \omega_0^2)^2 + \beta^2 \omega^2} \\ &\quad \times \cos(\omega t + \delta) \\ &= \frac{C}{\sqrt{\beta^2 \omega^2 + (\omega^2 - \omega_0^2)^2}} \cos(\omega t + \delta), \end{aligned} \quad (55)$$

where

$$\delta = \tan^{-1} \left( \frac{\beta \omega}{\omega^2 - \omega_0^2} \right). \quad (56)$$

Underdamped simple harmonic motion occurs when

$$\beta^2 - 4\omega_0^2 < 0, \quad (57)$$

so

$$\alpha \equiv \beta^2 - 4\omega_0^2 < 0. \quad (58)$$

The above plot shows an underdamped simple harmonic oscillator with  $\omega = 0.3$ ,  $\beta = 0.4$ . The solid curve is for  $(A, B) = (1, 0)$ , the dot-dashed for  $(0, 1)$ , and the dotted for  $(1/2, 1/2)$ . Define

$$\gamma \equiv \sqrt{-\alpha} = \frac{1}{2} \sqrt{4\omega_0^2 - \beta^2}, \quad (59)$$

then solutions satisfy

$$r_{\pm} = -\frac{1}{2}\beta \pm i\gamma, \quad (60)$$

where

$$r_{\pm} \equiv \frac{1}{2}(-\beta \pm \sqrt{\beta^2 - 4\omega_0^2}), \quad (61)$$

and are of the form

$$x = e^{-(\beta/2 \pm i\gamma)t}. \quad (62)$$

Using the EULER FORMULA

$$e^{ix} = \cos x + i \sin x, \quad (63)$$

this can be rewritten

$$x = e^{-(\beta/2)t} [\cos(\gamma t) \pm i \sin(\gamma t)]. \quad (64)$$

We are interested in the *real* solutions. Since we are dealing here with a *linear homogeneous* ODE, linear sums of LINEARLY INDEPENDENT solutions are also solutions. Since we have a sum of such solutions in (64), it follows that the IMAGINARY and REAL PARTS separately satisfy the ODE and are therefore the solutions we seek. The constant in front of the sine term is arbitrary, so we can identify the solutions as

$$x_1 = e^{-(\beta/2)t} \cos(\gamma t) \quad (65)$$

$$x_2 = e^{-(\beta/2)t} \sin(\gamma t), \quad (66)$$

so the general solution is

$$x = e^{-(\beta/2)t} [A \cos(\gamma t) + B \sin(\gamma t)]. \quad (67)$$

The initial values are

$$x(0) = A \quad (68)$$

$$x'(0) = -\frac{1}{2}\beta A + B, \gamma \quad (69)$$

so  $A$  and  $B$  can be expressed in terms of the initial conditions by

$$A = x(0) \quad (70)$$

$$B = \frac{\beta x(0)}{2\gamma} + \frac{x'(0)}{\gamma}. \quad (71)$$

For a cosinusoidally forced underdamped oscillator with forcing function  $g(t) = C \cos(\omega t)$ , use

$$\gamma \equiv \frac{1}{2} \sqrt{4\omega_0^2 - \beta^2} \quad (72)$$

$$\alpha \equiv \frac{1}{2} \beta \quad (73)$$

to obtain

$$4\omega_0^2 - \beta^2 = 4\gamma^2 \quad (74)$$

$$\omega_0^2 = \gamma^2 + \frac{1}{4}\beta^2 = \gamma^2 + \alpha^2 \quad (75)$$

$$\beta = 2\alpha. \quad (76)$$

The particular solutions are

$$y_1(t) = e^{-\alpha t} \cos(\gamma t) \quad (77)$$

$$y_2(t) = e^{-\alpha t} \sin(\gamma t). \quad (78)$$

The WRONSKIAN is

$$\begin{aligned} W(t) &\equiv y_1 y_2' - y_1' y_2 \\ &= e^{-\alpha t} \cos(\gamma t) [-\alpha e^{-\alpha t} \sin(\gamma t) + e^{-\alpha t} \gamma \cos(\gamma t)] \\ &\quad - e^{-\alpha t} \sin(\gamma t) [-\alpha e^{-\alpha t} \cos(\gamma t) - e^{-\alpha t} \gamma \sin(\gamma t)] \\ &= e^{-2\alpha t} \{ \alpha [-\sin(\gamma t) \cos(\gamma t) + \sin(\gamma t) \cos(\gamma t)] \\ &\quad + \gamma [\cos^2(\gamma t) + \sin^2(\gamma t)] \} \\ &= \gamma e^{-2\alpha t}. \end{aligned} \quad (79)$$

The particular solution is given by

$$y_p = -y_1 v_1 + y_2 v_2, \quad (80)$$

where

$$v_1 \equiv \int \frac{y_2 g(t)}{W(t)} dt = \frac{C}{\gamma} \int e^{\alpha t} \cos(\gamma t) \cos(\omega t) dt \quad (81)$$

$$v_2 \equiv \int \frac{y_1 g(t)}{W(t)} dt = \frac{C}{\gamma} \int e^{\alpha t} \sin(\gamma t) \cos(\omega t) dt. \quad (82)$$

Using computer algebra to perform the algebra, the particular solution is

$$\begin{aligned} y_p(t) &= C \frac{(\alpha^2 + \gamma^2 - \omega^2) \cos(\omega t) + 2\alpha\omega \sin(\omega t)}{[\alpha^2 + (\gamma - \omega)^2][\alpha^2 + (\gamma + \omega)^2]} \\ &= C \frac{(\omega_0^2 - \omega^2) \cos(\omega t) + \beta\omega \sin(\omega t)}{(\alpha^2 + \gamma^2 + \omega^2)^2 - 4\gamma^2\omega^2} \\ &= C \frac{(\omega_0^2 - \omega^2) \cos(\omega t) + \beta\omega \sin(\omega t)}{(\omega_0^2 + \omega^2)^2 - 4\frac{1}{4}(4\omega_0^2 - \beta^2)\omega^2} \\ &= C \frac{(\omega_0^2 - \omega^2) \cos(\omega t) + \beta\omega \sin(\omega t)}{(\omega_0^2 - \omega^2)^2 - \omega^2(4\omega_0^2 - \beta^2)} \\ &= \frac{C \sqrt{(\omega_0^2 - \omega^2)^2 + \beta^2\omega^2}}{(\omega_0^2 - \omega^2)^2 - \omega^2(4\omega_0^2 - \beta^2)} \cos(\omega t + \delta) \\ &= C \frac{\sqrt{(\omega_0^2 - \omega^2)^2 + \beta^2\omega^2}}{(\omega_0^2 - \omega^2)^2 - \omega^2(4\omega_0^2 - \beta^2)} \cos(\omega t + \delta), \end{aligned} \quad (83)$$

where

$$\delta = \tan^{-1} \left( \frac{\beta\omega}{\omega^2 - \omega_0^2} \right). \quad (84)$$

If the forcing function is sinusoidal instead of cosinusoidal, then

$$\delta' = \delta - \frac{1}{2}\pi = \tan^{-1} x - \frac{1}{2}\pi = \tan^{-1} \left( -\frac{1}{x} \right), \quad (85)$$

so

$$\delta' = \tan^{-1} \left( \frac{\omega_0^2 - \omega^2}{\beta\omega} \right). \quad (86)$$

### Simple Harmonic Motion Quadratic Perturbation

Given a simple harmonic oscillator with a quadratic perturbation  $\epsilon x^2$ ,

$$\ddot{x} + \omega_0^2 x - \alpha \epsilon x^2 = 0, \quad (1)$$

find the first-order solution using a perturbation method. Write

$$x \equiv x_0 + \epsilon x_1 + \dots, \quad (2)$$

so

$$\ddot{x} \equiv \ddot{x}_0 + \epsilon \ddot{x}_1 + \dots \quad (3)$$

Plugging (2) and (3) back into (1) gives

$$(\ddot{x}_0 + \epsilon \ddot{x}_1) + (\omega_0^2 x_0 + \omega_0^2 \epsilon x_1) - \alpha \epsilon (x_0 + 2x_0 x_1 \epsilon + \dots) = 0. \quad (4)$$

Keeping only terms of order  $\epsilon$  and lower and grouping, we obtain

$$(\ddot{x}_0 + \omega_0^2 x_0) + (\ddot{x}_1 + \omega_0^2 x_1 - \alpha x_0^2) \epsilon = 0. \quad (5)$$

Since this equation must hold for all POWERS of  $\epsilon$ , we can separate it into the two differential equations

$$\ddot{x}_0 + \omega_0^2 x_0 = 0 \quad (6)$$

$$\ddot{x}_1 + \omega_0^2 x_1 = \alpha x_0^2. \quad (7)$$

The solution to (6) is just

$$x_0 = A \cos(\omega_0 t + \phi). \quad (8)$$

Setting our clock so that  $\phi = 0$  gives

$$x_0 = A \cos(\omega_0 t). \quad (9)$$

Plugging this into (7) then gives

$$\ddot{x}_1 + \omega_0^2 x_1 = \alpha A^2 \cos^2(\omega_0 t). \quad (10)$$

The two homogeneous solutions to (10) are

$$x_1 = \cos(\omega_0 t) \quad (11)$$

$$x_2 = \sin(\omega_0 t). \quad (12)$$

The particular solution to (10) is therefore given by

$$x_p(t) = -x_1(t) \int \frac{x_2(t)g(t)}{W(t)} dt + x_2(t) \int \frac{x_1(t)g(t)}{W(t)} dt, \quad (13)$$

where

$$g(t) = \alpha A^2 \cos^2(\omega_0 t), \quad (14)$$

and the WRONSKIAN is

$$\begin{aligned} W &\equiv x_1 \dot{x}_2 - \dot{x}_1 x_2 \\ &= \cos(\omega_0 t) \omega_0 \cos(\omega_0 t) - [-\omega_0 \sin(\omega_0 t)] \sin(\omega_0 t) \\ &= \omega_0. \end{aligned} \quad (15)$$

Plugging everything into (13),

$$\begin{aligned} x_p &= \alpha A^2 \left[ -\cos(\omega_0 t) \int \frac{\sin(\omega_0 t) \cos^2(\omega_0 t)}{\omega_0} dt \right. \\ &\quad \left. + \sin(\omega_0 t) \int \frac{\cos^3(\omega_0 t)}{\omega_0} dt \right] \\ &= \frac{\alpha A^2}{\omega_0} \left\{ \sin(\omega_0 t) \int [1 - \sin^2(\omega_0 t)] \cos(\omega_0 t) dt \right. \\ &\quad \left. - \cos(\omega_0 t) \int \sin(\omega_0 t) \cos^2(\omega_0 t) dt \right\}. \end{aligned} \quad (16)$$

Now let

$$u \equiv \sin(\omega_0 t) \quad (17)$$

$$du = \omega_0 \cos(\omega_0 t) dt \quad (18)$$

$$v \equiv \cos(\omega_0 t) \quad (19)$$

$$dv = -\omega_0 \sin(\omega_0 t) dt. \quad (20)$$

Then

$$\begin{aligned} x_p &= \frac{\alpha A^2}{\omega_0^2} \left[ \sin(\omega_0 t) \int (1 - u^2) du + \cos(\omega_0 t) \int v^2 dv \right] \\ &= \frac{\alpha A^2}{\omega_0^2} \left[ \sin(\omega_0 t) \left(1 - \frac{1}{3} u^3\right) + \cos(\omega_0 t) \frac{1}{3} v^3 \right] \\ &= \frac{\alpha A^2}{\omega_0^2} \left\{ \sin(\omega_0 t) \left[1 - \frac{1}{3} \sin^3(\omega_0 t)\right] \right. \\ &\quad \left. + \frac{1}{3} \cos(\omega_0 t) \cos^3(\omega_0 t) \right\} \\ &= \frac{\alpha A^2}{\omega_0^2} \left\{ \frac{1}{3} [\cos^4(\omega_0 t) - \sin^4(\omega_0 t)] + \sin^2(\omega_0 t) \right\} \\ &= \frac{\alpha A^2}{\omega_0^2} \left\{ \frac{1}{3} [\cos^2(\omega_0 t) - \sin^2(\omega_0 t)] + \sin^2(\omega_0 t) \right\} \\ &= \frac{\alpha A^2}{\omega_0^2} \frac{1}{3} [\cos^2(\omega_0 t) + 2 \sin^2(\omega_0 t)] \\ &= \frac{\alpha A^2}{3 \omega_0^2} [2 - \cos^2(\omega_0 t)] = \frac{\alpha A^2}{3 \omega_0^2} \left\{ 2 - \frac{1}{2} [1 + \cos(2\omega_0 t)] \right\} \\ &= \frac{\alpha A^2}{6 \omega_0^2} [3 - \cos(2\omega_0 t)]. \end{aligned} \quad (21)$$

Plugging  $x_0(t)$  and (21) into (2), we obtain the solution

$$x(t) = A \cos(\omega_0 t) - \frac{\alpha A^2}{6 \omega_0^2} \epsilon [\cos(2\omega_0 t) - 3]. \quad (22)$$

## Simple Harmonic Oscillator

see SIMPLE HARMONIC MOTION

## Simple Interest

INTEREST which is paid only on the PRINCIPAL and not on the additional amount generated by previous INTEREST payments. A formula for computing simple interest is

$$a(t) = a(0)(1 + rt),$$

where  $a(t)$  is the sum of PRINCIPAL and INTEREST at time  $t$  for a constant interest rate  $r$ .

see also COMPOUND INTEREST, INTEREST

## References

Kellison, S. G. *Theory of Interest*, 2nd ed. Burr Ridge, IL: Richard D. Irwin, 1991.

## Simple Polygon

A POLYGON  $P$  is said to be simple (or JORDAN) if the only points of the plane belonging to two EDGES of  $P$  are the VERTICES of  $P$ . Such a polygon has a well-defined interior and exterior.

see also POLYGON, REGULAR POLYGON, TWO-EARS THEOREM

## References

Toussaint, G. "Anthropomorphic Polygons." *Amer. Math. Monthly* **122**, 31-35, 1991.

## Simple Ring

A NONZERO RING  $S$  whose only (two-sided) IDEALS are  $S$  itself and zero. Every commutative simple ring is a FIELD. Every simple ring is a PRIME RING.

see also FIELD, IDEAL, PRIME RING, RING

## Simplex

The generalization of a tetrahedral region of space to  $n$ -D. The boundary of a  $k$ -simplex has  $k + 1$  0-faces (VERTICES),  $k(k + 1)/2$  1-faces (EDGES), and  $\binom{k+1}{i+1}$   $i$ -faces, where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT.

The simplex in 4-D is a regular TETRAHEDRON  $ABCD$  in which a point  $E$  along the fourth dimension through the center of  $ABCD$  is chosen so that  $EA = EB = EC = ED = AB$ . The 4-D simplex has SCHLÄFLI SYMBOL  $\{3, 3, 3\}$ .

$n$	Simplex
0	point
1	line segment
2	equilateral triangular plane region
3	tetrahedral region
4	4-simplex

The only irreducible spherical simplexes generated by reflection are  $A_n$  ( $n \geq 1$ ),  $B_n$  ( $n \geq 4$ ),  $C_n$  ( $n \geq 2$ ),  $D_2^p$  ( $p \geq 5$ ),  $E_6$ ,  $E_7$ ,  $E_8$ ,  $F_4$ ,  $G_3$ , and  $G_4$ . The only irreducible Euclidean simplexes generated by reflection

are  $W_2$ ,  $P_m$  ( $m \geq 3$ ),  $Q_m$  ( $m \geq 5$ ),  $R_m$  ( $m \geq 3$ ),  $S_m$  ( $m \geq 4$ ),  $V_3$ ,  $T_7$ ,  $T_8$ ,  $T_9$ , and  $U_5$ .

The regular simplex in  $n$ -D with  $n \geq 5$  is denoted  $\alpha_n$  and has SCHLÄFLI SYMBOL  $\underbrace{\{3, \dots, 3\}}_{3^n - 1}$ .

### Simplex Method

A method for solving problems in LINEAR PROGRAMMING. This method, invented by G. B. Dantzig in 1947, runs along EDGES of the visualization SOLID to find the best answer. In 1970, Klee and Minty constructed examples in which the simplex method required an exponential number of steps, but such cases seem never to be encountered in practical applications.

A much more efficient (POLYNOMIAL-time) ALGORITHM was found in 1984 by N. Karmarkar. This method goes through the middle of the SOLID and then transforms and warps. It offers many advantages over the simplex method (Nemirovsky and Yudin 1994).

### Simplicial Complex

A simplicial complex is a SPACE with a TRIANGULATION. Objects in the space made up of only the simplices in the triangulation of the space are called simplicial subcomplexes. When only simplicial complexes and subcomplexes are considered, defining HOMOLOGY is particularly easy (and, in fact, combinatorial because of its finite/counting nature). This kind of homology is called SIMPLICIAL HOMOLOGY.

see also HOMOLOGY (TOPOLOGY), NERVE, SIMPLICIAL HOMOLOGY, SPACE, TRIANGULATION

### Simplicial Homology

The type of HOMOLOGY which results when the spaces being studied are restricted to SIMPLICIAL COMPLEXES and subcomplexes.

see also SIMPLICIAL COMPLEX

### Simplicity

The number of operations needed to effect a GEOMETRIC CONSTRUCTION as determined in GEOMETROGRAPHY. If the number of operations of the five GEOMETROGRAPHIC types are denoted  $m_1$ ,  $m_2$ ,  $n_1$ ,  $n_2$ , and  $n_3$ , respectively, then the simplicity is  $m_1 + m_2 + n_1 + n_2 + n_3$  and the symbol  $m_1S_1 + m_2S_2 + n_1C_1 + n_2C_2 + n_3C_3$ . It is apparently an unsolved problem to determine if a given GEOMETRIC CONSTRUCTION is of smallest possible simplicity.

### Simply Connected

A CONNECTED DOMAIN is said to be simply connected (also called 1-connected) if any simple closed curve can be shrunk to a point continuously in the set. If the domain is CONNECTED but not simply, it is said to be MULTIPLY CONNECTED.

A SPACE  $S$  is simply connected if it is 0-connected and if every MAP from the 1-SPHERE to  $S$  extends continuously to a MAP from the 2-DISK. In other words, every loop in the SPACE is contractible.

see also CONNECTED SPACE, MULTIPLY CONNECTED

### Simpson's Paradox

It is not necessarily true that averaging the averages of different populations gives the average of the combined population.

### Simpson's Rule

Let  $h \equiv (b-a)/n$ , and assume a function  $f(x)$  is defined at points  $f(a+kh) = y_k$  for  $k = 0, \dots, n$ . Then

$$\int_a^b f(x) dx = \frac{1}{3}h(y_1 + 4y_2 + 2y_3 + 4y_4 + \dots + 2y_{n-2} + 4y_{n-1} + y_n) - R_n,$$

where the remainder is

$$R_n = \frac{1}{90}(b-a)^4 f^{(4)}(x^*)$$

for some  $x^* \in [a, b]$ .

## Simson Line

The Simson line is the LINE containing the feet of the perpendiculars from a point on the CIRCUMCIRCLE of a TRIANGLE to the sides (or their extensions) of the TRIANGLE. The Simson line is sometimes known as the WALLACE-SIMPSON LINE, since it does not appear in any work of Simson (Johnson 1929, p. 137).

The ANGLE between the Simson lines of two points  $P$  and  $P'$  is half the ANGLE of the arc  $PP'$ . The Simson line of any VERTEX is the ALTITUDE through that VERTEX. The Simson line of a point opposite a VERTEX is the corresponding side. If  $T_1T_2T_3$  is the Simson line of a point  $T$  of the CIRCUMCIRCLE, then the triangles  $TT_1T_2$  and  $TA_2A_1$  are directly similar.

see also CIRCUMCIRCLE

## Sinc Function

A function also called the SAMPLING FUNCTION and defined by

$$\text{sinc}(x) \equiv \begin{cases} 1 & \text{for } x = 0 \\ \frac{\sin x}{x} & \text{otherwise,} \end{cases} \quad (1)$$

where  $\sin x$  is the SINE function. Let  $\Pi(x)$  be the RECTANGLE FUNCTION, then the FOURIER TRANSFORM of  $\Pi(x)$  is the sinc function

$$\mathcal{F}[\Pi(x)] = \text{sinc}(\pi k). \quad (2)$$

The sinc function therefore frequently arises in physical applications such as Fourier transform spectroscopy as the so-called INSTRUMENT FUNCTION, which gives the instrumental response to a DELTA FUNCTION input. Removing the instrument functions from the final spectrum requires use of some sort of DECONVOLUTION algorithm.

The sinc function can be written as a complex INTEGRAL by noting that

$$\begin{aligned} \text{sinc}(nx) &\equiv \frac{\sin(nx)}{nx} = \frac{1}{nx} \frac{e^{inx} - e^{-inx}}{2i} \\ &= \frac{1}{2inx} [e^{itx}]_{-n}^n = \frac{1}{2n} \int_{-n}^n e^{itx} dt. \end{aligned} \quad (3)$$

The sinc function can also be written as the INFINITE PRODUCT

$$\frac{\sin x}{x} = \prod_{k=1}^{\infty} \cos\left(\frac{x}{2^k}\right). \quad (4)$$

Definite integrals involving the sinc function include

$$\int_0^{\infty} \text{sinc}(x) dx = \frac{1}{2}\pi \quad (5)$$

$$\int_0^{\infty} \text{sinc}^2(x) dx = \frac{1}{2}\pi \quad (6)$$

$$\int_0^{\infty} \text{sinc}^3(x) dx = \frac{3}{8}\pi \quad (7)$$

$$\int_0^{\infty} \text{sinc}^4(x) dx = \frac{1}{3}\pi \quad (8)$$

$$\int_0^{\infty} \text{sinc}^5(x) dx = \frac{115}{384}\pi. \quad (9)$$

These are all special cases of the amazing general result

$$\int_0^\infty \frac{\sin^a x}{x^b} dx = \frac{\pi^{1-c} (-1)^{\lfloor (a-b)/2 \rfloor}}{2^{a-c} (b-1)!} \times \sum_{k=0}^{\lfloor a/2 \rfloor - c} (-1)^k \binom{a}{k} (a-2k)^{b-1} [\ln(a-2k)]^c, \quad (10)$$

where  $a$  and  $b$  are POSITIVE integers such that  $a \geq b > c$ ,  $c \equiv a-b \pmod{2}$ ,  $\lfloor x \rfloor$  is the FLOOR FUNCTION, and  $0^0$  is taken to be equal to 1 (Kogan). This spectacular formula simplifies in the special case when  $n$  is a POSITIVE EVEN integer to

$$\int_0^\infty \frac{\sin^{2n} x}{x^{2n}} dx = \frac{\pi}{2(2n-1)!} \left\langle \frac{2n-1}{n-1} \right\rangle, \quad (11)$$

where  $\left\langle \frac{n}{k} \right\rangle$  is an EULERIAN NUMBER (Kogan). The solution of the integral can also be written in terms of the RECURRENCE RELATION for the coefficients

$$c(a, b) = \begin{cases} \frac{\pi}{2^{a+1-b}} \left( \frac{1}{2} \binom{a-1}{b-1} \right) & \text{for } b=1 \text{ or } b=2 \\ \frac{a}{(b-1)(b-2)} [(a-1)c(a-2, b-2) - a \cdot c(a, b-2)] & \text{otherwise} \end{cases} \quad (12)$$

(Zimmerman).

The half-infinite integral of  $\text{sinc}(x)$  can be derived using CONTOUR INTEGRATION. In the above figure, consider the path  $\gamma \equiv \gamma_1 + \gamma_{12} + \gamma_2 + \gamma_{21}$ . Now write  $z = Re^{i\theta}$ . On an arc,  $dz = iRe^{i\theta} d\theta$  and on the  $x$ -AXIS,  $dz = e^{i\theta} dR$ . Write

$$\int_{-\infty}^\infty \frac{\sin x}{x} dx = \Im \int_\gamma \frac{e^{iz}}{z} dz, \quad (13)$$

where  $\Im$  denotes the IMAGINARY POINT. Now define

$$\begin{aligned} I &\equiv \int_\gamma \frac{e^{iz}}{z} dz \\ &= \lim_{R_1 \rightarrow 0} \int_\pi^0 \frac{\exp(iR_1 e^{i\theta})}{R_1 e^{i\theta}} i\theta R_1 e^{i\theta} d\theta \\ &\quad + \lim_{R_1 \rightarrow 0} \lim_{R_2 \rightarrow \infty} \int_{R_1}^{R_2} \frac{e^{iR}}{R} dR \\ &\quad + \lim_{R_2 \rightarrow \infty} \int_0^\pi \frac{\exp(iz)}{z} dz + \lim_{R_1 \rightarrow 0} \int_{R_2}^{R_1} \frac{e^{-iR}}{-R} (-dR), \end{aligned} \quad (14)$$

where the second and fourth terms use the identities  $e^{i0} = 1$  and  $e^{i\pi} = -1$ . Simplifying,

$$\begin{aligned} I &= \lim_{R_1 \rightarrow 0} \int_\pi^0 \exp(iR_1 e^{i\theta}) i\theta d\theta + \int_{0+}^\infty \frac{e^{iR}}{R} dR \\ &\quad + \lim_{R_2 \rightarrow \infty} \int_0^\pi \frac{\exp(iz)}{z} dz + \int_\infty^{0+} \frac{e^{-iR}}{-R} (-dR) \\ &= - \int_0^\pi i\theta d\theta + \int_{0+}^\infty \frac{e^{iR}}{R} dR + 0 + \int_{-\infty}^{0-} \frac{e^{iR}}{R} dR, \end{aligned} \quad (15)$$

where the third term vanishes by JORDAN'S LEMMA. Performing the integration of the first term and combining the others yield

$$I = -i\pi + \int_{-\infty}^\infty \frac{e^{iz}}{z} dz = 0. \quad (16)$$

Rearranging gives

$$\int_{-\infty}^\infty \frac{e^{iz}}{z} dz = i\pi, \quad (17)$$

so

$$\int_{-\infty}^\infty \frac{\sin z}{z} dz = \pi. \quad (18)$$

The same result is arrived at using the method of RESIDUES by noting

$$\begin{aligned} I &= 0 + \frac{1}{2} 2\pi i \text{Res}[f(z)]_{z=0} \\ &= i\pi \left[ (z-0) \frac{e^{iz}}{z} \right]_{z=0} = i\pi [e^{iz}]_{z=0} \\ &= i\pi, \end{aligned} \quad (19)$$

so

$$\Im(I) = \pi. \quad (20)$$

Since the integrand is symmetric, we therefore have

$$\int_0^\infty \frac{\sin x}{x} dx = \frac{1}{2}\pi, \quad (21)$$

giving the SINE INTEGRAL evaluated at 0 as

$$\text{si}(0) = - \int_0^\infty \frac{\sin x}{x} dx = -\frac{1}{2}\pi. \quad (22)$$

An interesting property of  $\text{sinc}(x)$  is that the set of LOCAL EXTREMA of  $\text{sinc}(x)$  corresponds to its intersections with the COSINE function  $\cos(x)$ , as illustrated above.

#### Sine

Let  $\theta$  be an ANGLE measured counterclockwise from the  $x$ -AXIS along the arc of the UNIT CIRCLE. Then  $\sin \theta$  is the vertical coordinate of the arc endpoint. As a result of this definition, the sine function is periodic with period  $2\pi$ . By the PYTHAGOREAN THEOREM,  $\sin \theta$  also obeys the identity

$$\sin^2 \theta + \cos^2 \theta = 1. \quad (1)$$

The sine function can be defined algebraically by the infinite sum

$$\sin x = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{(2n-1)!} x^{2n-1} \quad (2)$$

and INFINITE PRODUCT

$$\sin x = x \prod_{n=1}^{\infty} \left( 1 - \frac{x^2}{n^2 \pi^2} \right). \quad (3)$$

It is also given by the IMAGINARY PART of the complex exponential

$$\sin x = \Im[e^{ix}]. \quad (4)$$

The multiplicative inverse of the sine function is the COSECANT, defined as

$$\csc x \equiv \frac{1}{\sin x}. \quad (5)$$

Using the results from the EXPONENTIAL SUM FORMULAS

$$\begin{aligned} \sum_{n=0}^{\infty} \sin(nx) &= \Im \left[ \sum_{n=0}^{\infty} e^{inx} \right] \\ &= \Im \left[ \frac{\sin(\frac{1}{2}Nx)}{\sin(\frac{1}{2}x)} e^{i(N-1)x/2} \right] \\ &= \frac{\sin(\frac{1}{2}Nx)}{\sin(\frac{1}{2}x)} \sin[\frac{1}{2}x(N-1)]. \end{aligned} \quad (6)$$

Similarly,

$$\begin{aligned} \sum_{n=0}^{\infty} p^n \sin(nx) &= \Im \left[ \sum_{n=0}^{\infty} p^n e^{inx} \right] \\ &= \Im \left[ \frac{1 - pe^{-ix}}{1 - 2p \cos x + p^2} \right] = \frac{p \sin x}{1 - 2p \cos x + p^2}. \end{aligned} \quad (7)$$

Other identities include

$$\sin(n\theta) = 2 \cos \theta \sin[(n-1)\theta] - \sin[(n-2)\theta] \quad (8)$$

$$\begin{aligned} \sin(nx) &= \binom{n}{1} \cos^{n-1} x \sin x - \binom{n}{3} \cos^{n-3} x \sin^3 x \\ &\quad + \binom{n}{5} \cos^{n-5} x \sin^5 x - \dots, \end{aligned} \quad (9)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT.

Cvijović and Klinowski (1995) show that the sum

$$S_\nu(\alpha) = \sum_{k=0}^{\infty} \frac{\sin(2k+1)\alpha}{(2k+1)^\nu} \quad (10)$$

has closed form for  $\nu = 2n+1$ ,

$$S_{2n+1}(\alpha) = \frac{(-1)^n}{4(2n)!} \pi^{2n+1} E_{2n}\left(\frac{\alpha}{\pi}\right), \quad (11)$$

where  $E_n(x)$  is an EULER POLYNOMIAL.

A CONTINUED FRACTION representation of  $\sin x$  is

$$\sin x = \frac{x}{1 + \frac{x^2}{(2 \cdot 3 - x^2) + \frac{2 \cdot 3x^2}{(4 \cdot 5 - x^2) + \frac{4 \cdot 5x^2}{(6 \cdot 7 - x^2) + \dots}}}} \quad (12)$$

The value of  $\sin(2\pi/n)$  is IRRATIONAL for all  $n$  except 4 and 12, for which  $\sin(\pi/2) = 1$  and  $\sin(\pi/6) = 1/2$ .

The FOURIER TRANSFORM of  $\sin(2\pi k_0 x)$  is given by

$$\begin{aligned} \mathcal{F}[\sin(2\pi k_0 x)] &= \int_{-\infty}^{\infty} e^{-2\pi i k_0 x} \sin(2\pi k_0 x) dx \\ &= \frac{1}{2} i [\delta(k+k_0) - \delta(k-k_0)]. \end{aligned} \quad (13)$$

Definite integrals involving  $\sin x$  include

$$\int_0^{\infty} \sin(x^2) dx = \frac{1}{4} \sqrt{2\pi} \quad (14)$$

$$\int_0^{\infty} \sin(x^3) dx = \frac{1}{6} \Gamma\left(\frac{1}{3}\right) \quad (15)$$

$$\int_0^{\infty} \sin(x^4) dx = -\cos\left(\frac{5}{8}\pi\right) \Gamma\left(\frac{5}{4}\right) \quad (16)$$

$$\int_0^{\infty} \sin(x^5) dx = \frac{1}{4} (\sqrt{5} - 1) \Gamma\left(\frac{6}{5}\right), \quad (17)$$

where  $\Gamma(x)$  is the GAMMA FUNCTION.

#### Sine-Gordon Equation

A PARTIAL DIFFERENTIAL EQUATION which appears in differential geometry and relativistic field theory. Its name is a pun on its similar form to the KLEIN-GORDON EQUATION. The sine-Gordon equation is

$$v_{tt} - v_{xx} + \sin v = 0, \quad (1)$$

where  $v_{tt}$  and  $v_{xx}$  are PARTIAL DERIVATIVES. The equation can be transformed by defining

$$\xi \equiv \frac{1}{2}(x - t) \quad (2)$$

$$\eta \equiv \frac{1}{2}(x + t), \quad (3)$$

giving

$$v_{\xi\eta} = \sin v. \quad (4)$$

Traveling wave analysis gives

$$z - z_0 = \sqrt{c^2 - 1} \int \frac{df}{\sqrt{2[d - 2\sin^2(\frac{1}{2}f)]}}. \quad (5)$$

For  $d = 0$ ,

$$z - z_0 = \pm \sqrt{1 - c^2} \ln[\pm \tan(\frac{1}{4}f)] \quad (6)$$

$$f(z) = \pm 4 \tan^{-1}[e^{\pm(z-z_0)/(1-c^2)^{1/2}}]. \quad (7)$$

Letting  $z \equiv \xi\eta$  then gives

$$zf'' + f' = \sin f. \quad (8)$$

Letting  $g \equiv e^{if}$  gives

$$g'' - \frac{g'^2}{f} + \frac{2g' - g^2 + 1}{2z} = 0, \quad (9)$$

which is the third PAINLEVÉ TRANSCENDENT. Look for a solution of the form

$$v(x, t) = 4 \tan^{-1} \left[ \frac{\phi(x)}{\psi(t)} \right]. \quad (10)$$

Taking the partial derivatives gives

$$\phi_{xx} = -k^2 \phi^4 + m^2 \phi^2 + n^2 \quad (11)$$

$$\psi_{tt} = k^2 \psi^4 + (m^2 - 1)\psi^2 - n^2, \quad (12)$$

which can be solved in terms of ELLIPTIC FUNCTIONS. A single SOLITON solution exists with  $k = n = 0$ ,  $m > 1$ :

$$v = 4 \tan^{-1} \left[ \exp \left( \frac{\pm x - \beta t}{\sqrt{1 - \beta^2}} \right) \right], \quad (13)$$

where

$$\beta \equiv \frac{\sqrt{m^2 - 1}}{m}. \quad (14)$$

A two-SOLITON solution exists with  $k = 0$ ,  $m > 1$ :

$$v = 4 \tan^{-1} \left[ \frac{\sinh(\beta mx)}{\beta \cosh(\beta mt)} \right]. \quad (15)$$

A SOLITON-antisoliton solution exists with  $k \neq 0$ ,  $n = 0$ ,  $m^2 > 1$ :

$$v = -4 \tan^{-1} \left[ \frac{\sinh(\beta mx)}{\beta \cosh(mt)} \right]. \quad (16)$$

A “breather” solution is

$$v = -4 \tan^{-1} \left[ \frac{m}{\sqrt{1-m^2}} \frac{\sin(\sqrt{1-m^2}t)}{\cosh(mx)} \right]. \quad (17)$$

### Sine Integral

There are two types of “sine integrals” commonly defined,

$$\text{Si}(x) \equiv \int_0^x \frac{\sin t}{t} dt \quad (1)$$

and

$$\text{si}(x) \equiv - \int_x^\infty \frac{\sin t}{t} dt \quad (2)$$

$$= \frac{1}{2i} [\text{ei}(ix) - \text{ei}(-ix)]$$

$$= \frac{1}{2i} [e_1(ix) - e_1(-ix)] \quad (3)$$

$$= \text{Si}(z) - \frac{1}{2}\pi, \quad (4)$$

where  $\text{ei}(x)$  is the EXPONENTIAL INTEGRAL and

$$e_1(x) \equiv -\text{ei}(-x). \quad (5)$$

$\text{Si}(x)$  is the function returned by the *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) command `SinIntegral[x]` and displayed above. The half-infinite integral of the SINC FUNCTION is given by

$$\text{si}(0) = - \int_0^\infty \frac{\sin x}{x} dx = -\frac{1}{2}\pi. \quad (6)$$

To compute the integral of a sine function times a power

$$I \equiv \int x^{2n} \sin(mx) dx, \quad (7)$$

use INTEGRATION BY PARTS. Let

$$u = x^{2n} \quad dv = \sin(mx) dx \quad (8)$$

$$du = 2nx^{2n-1} dx \quad v = -\frac{1}{m} \cos(mx), \quad (9)$$

so

$$I = -\frac{1}{m} x^{2n} \cos(mx) + \frac{2n}{m} \int x^{2n-1} \cos(mx) dx. \quad (10)$$

Using INTEGRATION BY PARTS again,

$$u = x^{2n-1} \quad dv = \cos(mx) dx \quad (11)$$

$$du = (2n-1)x^{2n-2} dx \quad v = \frac{1}{m} \sin(mx) \quad (12)$$

$$\begin{aligned} \int x^{2n} \sin(mx) dx &= -\frac{1}{m} x^{2n} \cos(mx) \\ &+ \frac{2n}{m} \left[ \frac{1}{m} x^{2n-1} \cos(mx) \right. \\ &\quad \left. - \frac{2n-1}{m} \int x^{2n-2} \sin(mx) dx \right] \\ &= -\frac{1}{m} x^{2n} \sin(mx) + \frac{2n}{m^2} x^{2n-1} \sin(mx) \\ &\quad - \frac{(2n)(2n-1)}{m^2} \int x^{2n-2} \sin(mx) dx \\ &= -\frac{1}{m} x^{2n} \cos(mx) + \frac{2n}{m^2} x^{2n-1} \sin(mx) + \dots \\ &\quad + \frac{(2n)!}{m^{2n}} \int x^0 \sin(mx) dx \\ &= -\frac{1}{m} x^{2n} \cos(mx) + \frac{2n}{m^2} x^{2n-1} \sin(mx) + \dots \\ &\quad - \frac{(2n)!}{m^{2n+1}} \cos(mx) \\ &= \cos(mx) \sum_{k=0}^n (-1)^{k+1} \frac{(2n)!}{(2n-2k)! m^{2k+1}} x^{2n-2k} \\ &\quad + \sin(mx) \sum_{k=1}^n (-1)^{k+1} \frac{(2n)!}{(2k-2n-1)! m^{2k}} x^{2n-2k+1}. \end{aligned} \quad (13)$$

Letting  $k' \equiv n - k$ , so

$$\begin{aligned} & \int x^{2n} \sin(mx) dx \\ &= \cos(mx) \sum_{k=0}^n (-1)^{n-k+1} \frac{(2n)!}{(2k)! m^{2n-2k+1}} x^{2k} \\ &+ \sin(mx) \sum_{k=0}^{n-1} (-1)^{n-k+1} \frac{(2n)!}{(2k-1)! m^{2n-2k}} x^{2k+1} \\ &= (-1)^{n+1} (2n)! \left[ \cos(mx) \sum_{k=0}^n \frac{(-1)^k}{(2k)! m^{2n-2k+1}} x^{2k} \right. \\ &\quad \left. + \sin(mx) \sum_{k=1}^n \frac{(-1)^{k+1}}{(2k-1)! m^{2n-2k}} x^{2k+1} \right]. \end{aligned} \quad (14)$$

General integrals of the form

$$I(k, l) = \int_0^\infty \frac{\sin^k x}{x^l} dx \quad (15)$$

are related to the SINC FUNCTION and can be computed analytically.

#### Sine-Tangent Theorem

If

$$\frac{\sin \alpha}{\sin \beta} = \frac{m}{n},$$

then

$$\frac{\tan[\frac{1}{2}(\alpha - \beta)]}{\tan[\frac{1}{2}(\alpha + \beta)]} = \frac{m - n}{m + n}.$$

#### Sines Law

see LAW OF SINES

#### Singly Even Number

AN EVEN NUMBER of the form  $4n + 2$  (i.e., an INTEGER which is DIVISIBLE by 2 but not by 4). The first few for  $n = 0, 1, 2, \dots$  are 2, 6, 10, 14, 18, ... (Sloane's A016825)

see also DOUBLY EVEN NUMBER, EVEN NUMBER, ODD NUMBER

#### References

#### Singular Homology

The general type of HOMOLOGY which is what mathematicians generally mean when they say "homology." Singular homology is a more general version than Poincaré's original SIMPLICIAL HOMOLOGY.

see also HOMOLOGY (TOPOLOGY), SIMPLICIAL HOMOLOGY

#### Singular Point (Algebraic Curve)

A singular point of an ALGEBRAIC CURVE is a point where the curve has "nasty" behavior such as a CUSP or a point of self-intersection (when the underlying field  $K$  is taken as the REALS). More formally, a point  $(a, b)$  on a curve  $f(x, y) = 0$  is singular if the  $x$  and  $y$  PARTIAL DERIVATIVES of  $f$  are both zero at the point  $(a, b)$ . (If the field  $K$  is not the REALS or COMPLEX NUMBERS, then the PARTIAL DERIVATIVE is computed formally using the usual rules of CALCULUS.)

Consider the following two examples. For the curve

$$x^3 - y^2 = 0,$$

the CUSP at  $(0, 0)$  is a singular point. For the curve

$$x^2 + y^2 = -1,$$

$(0, i)$  is a nonsingular point and this curve is nonsingular.

see also ALGEBRAIC CURVE, CUSP

#### Singular Point (Differential Equation)

Consider a second-order ORDINARY DIFFERENTIAL EQUATION

$$y'' + P(x)y' + Q(x)y = 0.$$

If  $P(x)$  and  $Q(x)$  remain FINITE at  $x = x_0$ , then  $x_0$  is called an ORDINARY POINT. If either  $P(x)$  or  $Q(x)$  diverges as  $x \rightarrow x_0$ , then  $x_0$  is called a singular point. Singular points are further classified as follows:

1. If either  $P(x)$  or  $Q(x)$  diverges as  $x \rightarrow x_0$  but  $(x - x_0)P(x)$  and  $(x - x_0)^2 Q(x)$  remain FINITE as  $x \rightarrow x_0$ , then  $x = x_0$  is called a REGULAR SINGULAR POINT (or NONESSENTIAL SINGULARITY).

2. If  $P(x)$  diverges more quickly than  $1/(x - x_0)$ , so  $(x - x_0)P(x)$  approaches INFINITY as  $x \rightarrow x_0$ , or  $Q(x)$  diverges more quickly than  $1/(x - x_0)^2 Q$  so that  $(x - x_0)^2 Q(x)$  goes to INFINITY as  $x \rightarrow x_0$ , then  $x_0$  is called an IRREGULAR SINGULARITY (or ESSENTIAL SINGULARITY).

see also IRREGULAR SINGULARITY, REGULAR SINGULAR POINT, SINGULARITY

#### References

Arfken, G. "Singular Points." §8.4 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 451-454, 1985.

### Singular Point (Function)

Singular points (also simply called "singularities") are points  $z_0$  in the DOMAIN of a FUNCTION  $f$  where  $f$  fails to be ANALYTIC. ISOLATED SINGULARITIES may be classified as ESSENTIAL SINGULARITIES, POLES, or REMOVABLE SINGULARITIES.

ESSENTIAL SINGULARITIES are POLES of INFINITE order.

A POLE of order  $n$  is a singularity  $z_0$  of  $f(z)$  for which the function  $(z - z_0)^n f(z)$  is nonsingular and for which  $(z - z_0)^k f(z)$  is singular for  $k = 0, 1, \dots, n - 1$ .

REMOVABLE SINGULARITIES are singularities for which it is possible to assign a COMPLEX NUMBER in such a way that  $f(z)$  becomes ANALYTIC. For example, the function  $f(z) = z^2/z$  has a REMOVABLE SINGULARITY at 0, since  $f(z) = z$  everywhere but 0, and  $f(z)$  can be set equal to 0 at  $z = 0$ . REMOVABLE SINGULARITIES are not POLES.

The function  $f(z) = \csc(1/z)$  has POLES at  $z = 1/(2\pi n)$ , and a nonisolated singularity at 0.

see also ESSENTIAL SINGULARITY, IRREGULAR SINGULARITY, ORDINARY POINT, POLE, REGULAR SINGULAR POINT, REMOVABLE SINGULARITY, SINGULAR POINT (DIFFERENTIAL EQUATION)

#### References

Arfken, G. "Singularities." §7.1 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 396-400, 1985.

### Singular Series

$$\rho_{2s}(n) = \frac{\pi^s}{\Gamma(s)} n^{s-1} \sum_{p,q} \left( \frac{S_{p,q}}{q} \right)^{2s} e^{2\pi p n i/q},$$

where  $S_{p,q}$  is a GAUSSIAN SUM, and  $\Gamma(s)$  is the GAMMA FUNCTION.

### Singular System

A system is singular if the CONDITION NUMBER is INFINITE and ILL-CONDITIONED if it is too large.

see also CONDITION NUMBER, ILL-CONDITIONED

### Singular Value

A MODULUS  $k_r$  such that

$$\frac{K'(k_r)}{K(k_r)} = \sqrt{r},$$

where  $K(k)$  is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and  $K'(k_r) \equiv K(\sqrt{1 - k_r^2})$ . The ELLIPTIC LAMBDA FUNCTION  $\lambda^*(r)$  gives the value of  $k_r$ .

Abel (quoted in Whittaker and Watson 1990, p. 525) proved that if  $r$  is an INTEGER, or more generally whenever

$$\frac{K'(k)}{K(k)} = \frac{a + b\sqrt{n}}{c + d\sqrt{n}},$$

where  $a, b, c, d$ , and  $n$  are INTEGERS, then the MODULUS  $k$  is the ROOT of an algebraic equation with INTEGER COEFFICIENTS.

see also ELLIPTIC INTEGRAL SINGULAR VALUE, ELLIPTIC INTEGRAL OF THE FIRST KIND, ELLIPTIC LAMBDA FUNCTION, MODULUS (ELLIPTIC INTEGRAL)

#### References

Whittaker, E. T. and Watson, G. N. *A Course in Modern Analysis*, 4th ed. Cambridge, England: Cambridge University Press, pp. 524-528, 1990.

### Singular Value Decomposition

An expansion of a REAL  $M \times N$  MATRIX by ORTHOGONAL OUTER PRODUCTS according to

$$A = \sum_{k=1}^K s_k \mathbf{u}_k \mathbf{v}_k^T, \quad (1)$$

where  $s_1 \geq s_2 \geq \dots \geq 0$ ,

$$K \equiv \min\{M, N\} \quad (2)$$

and

$$\mathbf{u}_k^T \mathbf{u}_{k'} = \mathbf{v}_l^T \mathbf{v}_{k'} = \delta_{kk'}. \quad (3)$$

Here  $\delta_{ij}$  is the KRONECKER DELTA and  $\mathbf{A}^T$  is the MATRIX TRANSPOSE.

**Singularity**

In general, a point at which an equation, surface, etc., blows up or becomes DEGENERATE.

see also ESSENTIAL SINGULARITY, ISOLATED SINGULARITY, SINGULAR POINT (ALGEBRAIC CURVE), SINGULAR POINT (DIFFERENTIAL EQUATION), SINGULAR POINT (FUNCTION), WHITNEY SINGULARITY

**Sinh**

see HYPERBOLIC SINE

**Sink (Directed Graph)**

A vertex of a DIRECTED GRAPH with no exiting edges, also called a TERMINAL.

see also DIRECTED GRAPH, NETWORK, SOURCE

**Sink (Map)**

A stable fixed point of a MAP which, in a dissipative DYNAMICAL SYSTEM, is an ATTRACTOR.

see also ATTRACTOR, DYNAMICAL SYSTEM

**Sinusoidal Projection**

An equal AREA MAP PROJECTION.

$$x = (\lambda - \lambda_0) \cos \phi \quad (1)$$

$$y = \phi. \quad (2)$$

The inverse FORMULAS are

$$\phi = y \quad (3)$$

$$\lambda = \lambda_0 + \frac{x}{\cos \phi}. \quad (4)$$

Snyder, J. P. *Map Projections—A Working Manual*. U. S. Geological Survey Professional Paper 1395. Washington, DC: U. S. Government Printing Office, pp. 243–248, 1987.

**Sinusoidal Spiral**

A curve of the form

$$r^n = a^n \cos(n\theta)$$

with  $n$  RATIONAL, which is not a true SPIRAL. Sinusoidal spirals were first studied by Maclaurin. Special cases are given in the following table.

$n$	Curve
−2	hyperbola
−1	line
− $\frac{1}{2}$	parabola
− $\frac{1}{3}$	Tschirnhausen cubic
0	logarithmic spiral
$\frac{1}{3}$	Cayley sextic
$\frac{1}{2}$	cardioid
1	circle
2	Bernoulli lemniscate

**Sinusoidal Spiral Inverse Curve**

The INVERSE CURVE of a SINUSOIDAL SPIRAL

$$r = a^{(1/n)} [\cos(nt)]^{1/n}$$

with INVERSION CENTER at the origin and inversion radius  $k$  is another SINUSOIDAL SPIRAL

$$r = ka^{(1/n)} [\cos(nt)]^{1/n}.$$

**Sinusoidal Spiral Pedal Curve**

The PEDAL CURVE of a SINUSOIDAL SPIRAL

$$r = a^{(1/n)} [\cos(nt)]^{1/n}$$

with PEDAL POINT at the center is another SINUSOIDAL SPIRAL

$$x = \cos^{1+1/n}(nt) \cos[(n+1)t]$$

$$y = \cos^{1+1/n}(nt) \sin[(n+1)t].$$

### Sister Celine's Method

A method for finding RECURRENCE RELATIONS for hypergeometric polynomials directly from the series expansions of the polynomials. The method is effective and easily implemented, but usually slower than ZEILBERGER'S ALGORITHM. Given a sum  $f(n) = \sum_k F(n, k)$ , the method operates by finding a recurrence of the form

$$\sum_{i=0}^I \sum_{j=0}^J a_{ij}(n) F(n-j, k-i) = 0$$

by proceeding as follows (Petkovšek *et al.* 1996, p. 59):

1. Fix trial values of  $I$  and  $J$ .
2. Assume a recurrence formula of the above form where  $a_{ij}(n)$  are to be solved for.
3. Divide each term of the assumed recurrence by  $F(n, k)$  and reduce every ratio  $F(n-j, k-i)/F(n, k)$  by simplifying the ratios of its constituent factorials so that only RATIONAL FUNCTIONS in  $n$  and  $k$  remain.
4. Put the resulting expression over a common DENOMINATOR, then collect the numerator as a POLYNOMIAL in  $k$ .
5. Solve the system of linear equations that results after setting the coefficients of each power of  $k$  in the NUMERATOR to 0 for the unknown coefficients  $a_{ij}$ .
6. If no solution results, start again with larger  $I$  or  $J$ .

Under suitable hypotheses, a "fundamental theorem" (Verbaten 1974, Wilf and Zeilberger 1992, Petkovšek *et al.* 1996) guarantees that this algorithm always succeeds for large enough  $I$  and  $J$  (which can be estimated in advance). The theorem also generalizes to multivariate sums and to  $q$ - and multi- $q$ -sums (Wilf and Zeilberger 1992, Petkovšek *et al.* 1996).

### Site Percolation

site percolation

bond percolation

A PERCOLATION which considers the lattice vertices as the relevant entities (left figure).

see also BOND PERCOLATION, PERCOLATION THEORY

### Siteswap

A siteswap is a sequence encountered in JUGGLING in which each term is a POSITIVE integer, encoded in BINARY. The transition rule from one term to the next consists of changing some 0 to 1, subtracting 1, and then dividing by 2, with the constraint that the DIVISION by two must be exact. Therefore, if a term is EVEN, the bit to be changed must be the units bit. In siteswaps, the number of 1-bits is a constant.

Each transition is characterized by the bit position of the toggled bit (denoted here by the numeral on top of the arrow). For example,

$$111 \xrightarrow{5} 10011 \xrightarrow{2} 1011 \xrightarrow{5} 10101 \xrightarrow{1} 1011 \xrightarrow{2} 111 \\ \xrightarrow{6} 100011 \xrightarrow{3} 10101 \xrightarrow{3} 1110 \xrightarrow{0} 111 \xrightarrow{4} 1011 \dots$$

The second term is given from the first as follows: 000111 with bit 5 flipped becomes 100111, or 39. Subtract 1 to obtain 38 and divide by two to obtain 19, which is 10011.

see also JUGGLING

### Six-Color Theorem

To color any map on the SPHERE or the PLANE requires at most six-colors. This number can be easily be reduced to five, and the FOUR-COLOR THEOREM demonstrates that the NECESSARY number is, in fact, four.

see also FOUR-COLOR THEOREM, HEAWOOD CONJECTURE, MAP COLORING

### Skein Relationship

A relationship between KNOT POLYNOMIALS for links in different orientations (denoted below as  $L_+$ ,  $L_0$ , and  $L_-$ ). J. H. Conway was the first to realize that the ALEXANDER POLYNOMIAL could be defined by a relationship of this type.

see also ALEXANDER POLYNOMIAL, HOMFLY POLYNOMIAL, SIGNATURE (KNOT)

### Skeleton

The GRAPH obtained by collapsing a POLYHEDRON into the PLANE. The number of topologically distinct skeletons  $N(n)$  with  $n$  VERTICES is given in the following table.

$n$	$N(n)$
4	1
5	2
6	7

### References

Gardner, M. *Martin Gardner's New Mathematical Diversions from Scientific American*. New York: Simon and Schuster, p. 233, 1966.

### Skeleton Division

A LONG DIVISION in which most or all of the digits are replaced by a symbol (usually asterisks) to form a CRYPTARITHM.

see also CRYPTARITHM

### Skew Conic

Also known as a GAUCHE CONIC, SPACE CONIC, TWISTED CONIC, or CUBICAL CONIC SECTION. A third-order SPACE CURVE having up to three points in common with a plane and having three points in common with the plane at infinity. A skew cubic is determined by six points, with no four of them COPLANAR. A line is met by up to four tangents to a skew cubic.

A line joining two points of a skew cubic (REAL or conjugate imaginary) is called a SECANT of the curve, and a line having one point in common with the curve is called a SEMISECANT or TRANSVERSAL. Depending on the nature of the roots, the skew conic is classified as follows:

1. The three ROOTS are REAL and distinct (CUBICAL HYPERBOLA).
2. One root is REAL and the other two are COMPLEX CONJUGATES (CUBICAL ELLIPSE).
3. Two of the ROOTS coincide (CUBICAL PARABOLIC HYPERBOLA).
4. All three ROOTS coincide (CUBICAL PARABOLA).

see also CONIC SECTION, CUBICAL ELLIPSE, CUBICAL HYPERBOLA, CUBICAL PARABOLA, CUBICAL PARABOLIC HYPERBOLA

### Skew Field

A FIELD in which the commutativity of multiplication is not required, more commonly called a DIVISION ALGEBRA.

see also DIVISION ALGEBRA, FIELD

### Skew Lines

Two or more LINES which have no intersections but are not PARALLEL, also called AGONIC LINES. Since two LINES in the PLANE must intersect or be PARALLEL, skew lines can exist only in three or more DIMENSIONS.

see also GALLUCCI'S THEOREM, REGULUS

### Skew Polyomino

see also L-POLYOMINO, SQUARE POLYOMINO, STRAIGHT POLYOMINO, T-POLYOMINO

### Skew Quadrilateral

A four-sided QUADRILATERAL not contained in a plane. The problem of finding the minimum bounding surface of a skew quadrilateral was solved by Schwarz (1890) in terms of ABELIAN INTEGRALS and has the shape of a SADDLE. It is given by solving

$$(1 + f_y^2)f_{xx} - 2f_x f_y f_{xy} + (1 + f_x^2)f_{yy} = 0.$$

see also QUADRILATERAL

### Skew Symmetric Matrix

A MATRIX  $A$  where

$$A^T = -A,$$

with  $A^T$  denoting the MATRIX TRANSPOSE.

see also MATRIX TRANSPOSE, SYMMETRIC MATRIX

**Skewes Number**

The Skewes number (or first Skewes number) is the number  $Sk_1$  above which  $\pi(n) < Li(n)$  must fail (assuming that the RIEMANN HYPOTHESIS is true), where  $\pi(n)$  is the PRIME COUNTING FUNCTION and  $Li(n)$  is the LOG-ARITHMIC INTEGRAL.

$$Sk_1 = e^{e^{79}} \approx 10^{10^{10^{34}}}.$$

The Skewes number has since been reduced to  $e^{e^{27/4}} \approx 8.185 \times 10^{370}$  by te Riele (1987), although Conway and Guy (1996) claim that the best current limit is  $10^{1167}$ . In 1914, Littlewood proved that the inequality must, in fact, fail infinitely often.

The second Skewes number  $Sk_2$  is the number above which  $\pi(n) < Li(n)$  must fail (assuming that the RIEMANN HYPOTHESIS is false). It is much larger than the Skewes number  $Sk_1$ ,

$$Sk_2 = 10^{10^{10^{10^3}}}.$$

see also GRAHAM'S NUMBER, RIEMANN HYPOTHESIS

**Skewness**

The degree of asymmetry of a distribution. If the distribution has a longer tail less than the maximum, the function has NEGATIVE skewness. Otherwise, it has POSITIVE skewness. Several types of skewness are defined. The FISHER SKEWNESS is defined by

$$\gamma_1 = \frac{\mu_3}{\mu_2^{3/2}} = \frac{\mu_3}{\sigma^3}, \quad (1)$$

where  $\mu_3$  is the third MOMENT, and  $\mu_2^{1/2} \equiv \sigma$  is the STANDARD DEVIATION. The PEARSON SKEWNESS is defined by

$$\beta_1 = \left( \frac{\mu_3}{\sigma^3} \right)^2 = \gamma_1^2. \quad (2)$$

The MOMENTAL SKEWNESS is defined by

$$\alpha^{(m)} \equiv \frac{1}{2} \gamma_1. \quad (3)$$

The PEARSON MODE SKEWNESS is defined by

$$\frac{[\text{mean}] - [\text{mode}]}{\sigma}. \quad (4)$$

PEARSON'S SKEWNESS COEFFICIENTS are defined by

$$\frac{3[\text{mean}] - [\text{mode}]}{s} \quad (5)$$

and

$$\frac{3[\text{mean}] - [\text{median}]}{s}. \quad (6)$$

The BOWLEY SKEWNESS (also known as QUARTILE SKEWNESS COEFFICIENT) is defined by

$$\frac{(Q_3 - Q_2) - (Q_2 - Q_1)}{Q_3 - Q_1} = \frac{Q_1 - 2Q_2 + Q_3}{Q_3 - Q_1}, \quad (7)$$

where the  $Q$ s denote the INTERQUARTILE RANGES. The MOMENTAL SKEWNESS is

$$\alpha^{(m)} \equiv \frac{1}{2} \gamma = \frac{\mu_3}{2\sigma^3}. \quad (8)$$

An ESTIMATOR for the FISHER SKEWNESS  $\gamma_1$  is

$$g_1 = \frac{k_3}{k_2^{3/2}}, \quad (9)$$

where the  $k$ s are  $k$ -STATISTICS. The STANDARD DEVIATION of  $g_1$  is

$$\sigma_{g_1}^2 \approx \frac{6}{N}. \quad (10)$$

see also BOWLEY SKEWNESS, FISHER SKEWNESS, GAMMA STATISTIC, KURTOSIS, MEAN, MOMENTAL SKEWNESS, PEARSON SKEWNESS, STANDARD DEVIATION

**Sklar's Theorem**

Let  $H$  be a 2-D distribution function with marginal distribution functions  $F$  and  $G$ . Then there exists a COPULA  $C$  such that

$$H(x, y) = C(F(x), G(y)).$$

Conversely, for any univariate distribution functions  $F$  and  $G$  and any COPULA  $C$ , the function  $H$  is a two-dimensional distribution function with marginals  $F$  and  $G$ . Furthermore, if  $F$  and  $G$  are continuous, then  $C$  is unique.

# Skolem-Mahler-Lerch Theorem

If  $\{a_0, a_1, \dots\}$  is a RECURRENCE SEQUENCE, then the set of all  $k$  such that  $a_k = 0$  is the union of a finite (possibly EMPTY) set and a finite number (possibly zero) of full arithmetical progressions, where a full arithmetic progression is a set of the form  $\{r, r + d, r + 2d, \dots\}$  with  $r \in [0, d)$ .

# Skolem Paradox

Even though ARITHMETIC is uncountable, it possesses a countable "model."

# Skolem Sequence

A Skolem sequence of order  $n$  is a sequence  $S = \{s_1, s_2, \dots, s_{2n}\}$  of  $2n$  integers such that

1. For every  $k \in \{1, 2, \dots, n\}$ , there exist exactly two elements  $s_i, s_j \in S$  such that  $s_i = s_j = k$ , and
2. If  $s_i = s_j = k$  with  $i < j$ , then  $j - i = k$ .

# Slide Move

The REIDEMEISTER MOVE of type III.

see also REIDEMEISTER MOVES

# Slide Rule

A mechanical device consisting of a sliding portion and a fixed case, each marked with logarithmic axes. By lining up the ticks, it is possible to do MULTIPLICATION by taking advantage of the additive property of LOGARITHMS. More complicated slide rules also allow the extraction of roots and computation of trigonometric functions. The development of the desk calculator (and subsequently pocket calculator) rendered slide rules largely obsolete beginning in the 1960s.

see RUNNING KNOT

# Slope

A quantity which gives the inclination of a curve or line with respect to another curve or line. For a LINE in the PLANE making an ANGLE  $\theta$  with the  $x$ -AXIS, the SLOPE  $m$  is a constant given by

$$m \equiv \frac{\Delta y}{\Delta x} = \tan \theta,$$

where  $\Delta x$  and  $\Delta y$  are changes in the two coordinates over some distance. It is meaningless to talk about the slope in 3-D unless the slope *with respect to what* is specified.

see also MOVING AVERAGE

**Sluze Pearls**

see PEARLS OF SLUZE

**Smale-Hirsch Theorem**

The SPACE of IMMERSIONS of a MANIFOLD in another MANIFOLD is HOMOTOPICALLY equivalent to the space of bundle injections from the TANGENT SPACE of the first to the TANGENT BUNDLE of the second.

see also HOMOTOPY, IMMERSION, MANIFOLD, TANGENT BUNDLE, TANGENT SPACE

**Smale Horseshoe Map**

The basic topological operations for constructing an ATTRACTOR consist of stretching (which gives sensitivity to initial conditions) and folding (which gives the attraction). Since trajectories in PHASE SPACE cannot cross, the repeated stretching and folding operations result in an object of great topological complexity.

The Smale horseshoe map consists of a sequence of operations on the unit square. First, stretch by a factor of 2 in the  $x$  direction, then compress by  $2a$  in the  $y$  direction. Then, fold the rectangle and fit it back into the square. Repeating this generates the horseshoe attractor. If one looks at a cross-section of the final structure, it is seen to correspond to a CANTOR SET.

see also ATTRACTOR, CANTOR SET

An algorithm for computing a UNIT FRACTION.

**Small Number**

Guy's "STRONG LAW OF SMALL NUMBERS" states that there aren't enough small numbers to meet the many demands made of them. Guy (1988) also gives several interesting and misleading facts about small numbers:

1. 10% of the first 100 numbers are SQUARE NUMBERS.
2. A QUARTER of the numbers  $< 100$  are PRIMES.
3. All numbers less than 10, except for 6, are PRIME POWERS.
4. Half the numbers less than 10 are FIBONACCI NUMBERS.

see also LARGE NUMBER, STRONG LAW OF SMALL NUMBERS

References

Guy, R. K. "The Strong Law of Small Numbers." *Amer. Math. Monthly* **95**, 697-712, 1988.

**Small Retrosnub Icosicosidodecahedron**

The UNIFORM POLYHEDRON  $U_{72}$  also called the SMALL INVERTED RETROSNUB ICOSICOSIDODECAHEDRON whose DUAL POLYHEDRON is the SMALL HEXAGRAMMIC HEXECONTAHEDRON. It has WYTHOFF SYMBOL  $\frac{3}{2}\frac{3}{2}\frac{5}{2}$ . Its faces are  $100\{3\} + 12\{\frac{5}{2}\}$ . It has CIRCUMRADIUS with  $a = 1$

$$R = \frac{1}{4}\sqrt{13 + 3\sqrt{5} - \sqrt{102 + 46\sqrt{5}}} \\ \approx 0.580694800133921.$$

**Small Rhombicosidodecahedron**

An ARCHIMEDEAN SOLID whose DUAL POLYHEDRON is the DELTOIDAL HEXECONTAHEDRON. It has SCHLÄFLI SYMBOL  $r\left\{\frac{3}{5}\right\}$ . It is also UNIFORM POLYHEDRON  $U_{27}$  with WYTHOFF SYMBOL  $35|2$ . Its faces are  $20\{3\} + 30\{4\} + 12\{5\}$ . The SMALL DODECICOSIDODECAHEDRON and SMALL RHOMBIDODECAHEDRON are FACETED versions. The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for  $a = 1$  are

$$r = \frac{1}{41}(15 + 2\sqrt{5})\sqrt{11 + 4\sqrt{5}} = 2.12099\dots$$

$$\rho = \frac{1}{2}\sqrt{10 + 4\sqrt{5}} = 2.17625\dots$$

$$R = \frac{1}{2}\sqrt{11 + 4\sqrt{5}} = 2.23295\dots$$

see also GREAT RHOMBICOSIDODECAHEDRON (ARCHIMEDEAN), GREAT RHOMBICOSIDODECAHEDRON (UNIFORM)

### Small Rhombicuboctahedron

An ARCHIMEDEAN SOLID also (inappropriately) called the TRUNCATED ICOSIDODECAHEDRON. This name is inappropriate since truncation would yield rectangular instead of square faces. Its DUAL POLYHEDRON is the DELTOIDAL ICOSITETRAHEDRON, also called the TRAPEZOIDAL ICOSITETRAHEDRON. It has SCHLÄFLI SYMBOL  $r\left\{\frac{3}{4}\right\}$ . It is also UNIFORM POLYHEDRON  $U_{10}$  and has WYTHOFF SYMBOL  $34|2$ . Its INRADIUS, MIDRADIUS, and CIRCUMRADIUS for  $a = 1$  are

$$r = \frac{1}{17}(6 + \sqrt{2})\sqrt{5 + 2\sqrt{2}} = 1.22026\dots$$

$$\rho = \frac{1}{2}\sqrt{4 + 2\sqrt{2}} = 1.30656\dots$$

$$R = \frac{1}{2}\sqrt{5 + 2\sqrt{2}} = 1.39897\dots$$

A version in which the top and bottom halves are rotated with respect to each other is known as the ELONGATED SQUARE GYROBICUPOLA.

The small world problem asks for the probability that two people picked at random have at least one acquaintance in common.

see also BIRTHDAY PROBLEM

**Smarandache Ceil Function**

A SMARANDACHE-like function which is defined where  $S_k(n)$  is defined as the smallest integer for which  $n | S_k(n)^k$ . The Smarandache  $S_k(n)$  function can therefore be obtained by replacing any factors which are  $k$ th powers in  $n$  by their  $k$  roots. The functions  $S_k(n)$  for  $k = 2, 3, \dots, 6$  for values such that  $S_k(n) \neq n$  are tabulated by Begay (1997).

$S_1(n) = n$ , so the first few values of  $S_1(n)$  are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, ... (Sloane's A000027). The first few values of  $S_2(n)$  are 1, 2, 3, 2, 5, 6, 7, 4, 3, 10, 11, 6, 13, 14, 15, 4, 17, 6, 19, 10, ... (Sloane's A019554). The first few values of  $S_3(n)$  are 1, 2, 3, 2, 5, 6, 7, 2, 3, 10, 11, 6, 13, 14, 15, 4, 17, 6, 19, 10, ... (Sloane's A019555). The first few values of  $S_4(n)$  are 1, 2, 3, 2, 5, 6, 7, 2, 3, 10, 11, 6, 13, 14, 15, 2, 17, 6, 19, 10, ... (Sloane's A007947).

**Smarandache Constants**

The first Smarandache constant is defined as

$$S_1 \equiv \sum_{n=2}^{\infty} \frac{1}{[S(n)]!} > 1.093111,$$

where  $S(n)$  is the SMARANDACHE FUNCTION. Cojocaru and Cojocaru (1996a) prove that  $S_1$  exists and is bounded by  $0.717 < S_1 < 1.253$ . The lower limit given above is obtained by taking 40,000 terms of the sum.

Cojocaru and Cojocaru (1996b) prove that the second Smarandache constant

$$S_2 \equiv \sum_{n=2}^{\infty} \frac{S(n)}{n!} \approx 1.71400629359162$$

is an IRRATIONAL NUMBER.

Cojocaru and Cojocaru (1996c) prove that the series

$$S_3 \equiv \sum_{n=2}^{\infty} \frac{1}{\prod_{i=2}^n S(i)} \approx 0.719960700043708$$

converges to a number  $0.71 < S_3 < 1.01$ , and that

$$S_4(a) \equiv \sum_{n=2}^{\infty} \frac{n^a}{\prod_{i=2}^n S(i)}$$

converges for a fixed REAL NUMBER  $a \geq 1$ . The values for small  $a$  are

$$S_4(1) \approx 1.72875760530223$$

$$S_4(2) \approx 4.50251200619297$$

$$S_4(3) \approx 13.0111441949445$$

$$S_4(4) \approx 42.4818449849626$$

$$S_4(5) \approx 158.105463729329.$$

Sandor (1997) shows that the series

$$S_5 \equiv \sum_{n=1}^{\infty} \frac{(-1)^{n-1} S(n)}{n!}$$

converges to an IRRATIONAL. Burton (1995) and Dumitrescu and Seleacu (1996) show that the series

$$S_6 \equiv \sum_{n=2}^{\infty} \frac{S(n)}{(n+1)!}$$

converges. Dumitrescu and Seleacu (1996) show that the series

$$S_7 \equiv \sum_{n=r}^{\infty} \frac{S(n)}{(n+r)!}$$

and

$$S_8 \equiv \sum_{n=r}^{\infty} \frac{S(n)}{(n-r)!}$$

converge for  $r$  a natural number (which must be nonzero in the latter case). Dumitrescu and Seleacu (1996) show that

$$S_9 \equiv \sum_{n=2}^{\infty} \frac{1}{\sum_{i=2}^n \frac{S(i)}{i!}}$$

converges. Burton (1995) and Dumitrescu and Seleacu (1996) show that the series

$$S_{10} \sum_{n=2}^{\infty} \frac{1}{[S(n)]^{\alpha} \sqrt{S(n)!}}$$

and

$$S_{11} \sum_{n=2}^{\infty} \frac{1}{[S(n)]^{\alpha} \sqrt{[S(n)+1]!}}$$

converge for  $\alpha > 1$ .

#### Smarandache Function

The smallest value  $S(n)$  for a given  $n$  for which  $n|S(n)!$  ( $n$  divides  $S(n)$  FACTORIAL). For example, the number 8 does not divide  $1!$ ,  $2!$ ,  $3!$ , but does divide  $4! = 4 \cdot 3 \cdot 2 \cdot 1 = 8 \cdot 3$ , so  $S(8) = 4$ . For a PRIME  $p$ ,  $S(p) = p$ , and for an EVEN PERFECT NUMBER  $r$ ,  $S(r)$  is PRIME (Ashbacher 1997).

The Smarandache numbers for  $n = 1, 2, \dots$  are 1, 2, 3, 4, 5, 3, 7, 4, 6, 5, 11, ... (Sloane's A002034). Letting  $a(n)$  denote the smallest value of  $n$  for which  $S(n) = 1, 2, \dots$ , then  $a(n)$  is given by 1, 2, 3, 4, 5, 9, 7, 32, 27, 25, 11, 243, ... (Sloane's A046021). Some values of  $S(n)$  first occur only for very large  $n$ , for example,  $S(59,049) = 24$ ,  $S(177,147) = 27$ ,  $S(134,217,728) = 30$ ,  $S(43,046,721) = 36$ , and  $S(9,765,625) = 45$ . D. Wilson points out that if we let

$$I(n, p) = \frac{n - \Sigma(n, p)}{p - 1},$$

be the power of the PRIME  $p$  in  $n!$ , where  $\Sigma(n, p)$  is the sum of the base- $p$  digits of  $n$ , then it follows that

$$a(n) = \min p^{I(n-1, p)+1},$$

where the minimum is taken over the PRIMES  $p$  dividing  $n$ . This minimum appears to always be achieved when  $p$  is the GREATEST PRIME FACTOR of  $n$ .

The incrementally largest values of  $S(n)$  are 1, 2, 3, 4, 5, 7, 11, 13, 17, 19, 23, 29, ... (Sloane's A046022), which occur for  $n = 1, 2, 3, 4, 5, 7, 11, 13, 17, 19, 23, 29, \dots$ , i.e., the values where  $S(n) = n$ .

Tutescu (1996) conjectures that the DIOPHANTINE EQUATION  $S(n) = S(n+1)$  has no solution.

### Smarandache-Kurepa Function

Given the sum-of-factorials function

$$\Sigma(n) = \sum_{k=1}^n k!,$$

$SK(p)$  is the smallest integer for  $p$  PRIME such that  $1 + \Sigma[SK(p-1)]$  is divisible by  $p$ . The first few known values of  $SK(p)$  are 2, 4, 6, 6, 5, 7, 7, 12, 22, 16, 55, 54, 42, 24, ... for  $p = 2, 5, 7, 11, 17, 19, 23, 31, 37, 41, 61, 71, 73, 89, \dots$ . The values for  $p = 3, 13, 29, 43, 47, 53, 67, 79, 83, \dots$ , if they are finite, must be very large (e.g.,  $SK(3) > 100,000$ ).

### Smarandache Near-to-Primorial Function

$SNTP(n)$  is the smallest PRIME such that  $p\# - 1, p\#$ , or  $p\# + 1$  is divisible by  $n$ , where  $p\#$  is the PRIMORIAL of  $p$ . Ashbacher (1996) shows that  $SNTP(n)$  only exists

1. If there are no square or higher powers in the factorization of  $n$ , or
2. If there exists a PRIME  $q < p$  such that  $n|(q\# \pm 1)$ , where  $p$  is the smallest power contained in the factorization of  $n$ .

Therefore,  $SNTP(n)$  does not exist for the SQUAREFUL numbers  $n = 4, 8, 9, 12, 16, 18, 20, 24, 25, 27, 28, \dots$

(Sloane's A002997) The first few values of  $SNTP(n)$ , where defined, are 2, 2, 2, 3, 3, 3, 5, 7, ... (Sloane's A046026).

### Smarandache Paradox

Let  $A$  be some attribute (e.g., possible, present, perfect, etc.). If all is  $A$ , then the non- $A$  must also be  $A$ . For example, "All is possible, the impossible too," and "Nothing is perfect, not even the perfect."

### Smarandache Sequences

Smarandache sequences are any of a number of simply generated INTEGER SEQUENCES resembling those considered in published works by Smarandache such as the CONSECUTIVE NUMBER SEQUENCES and EUCLID NUMBERS (Iacobescu 1997). Other Smarandache-type sequences are given below.

1. The concatenation of  $n$  copies of the INTEGER  $n$ : 1, 22, 333, 4444, 55555, ... (Sloane's A000461; Marimutha 1997),
2. The concatenation of the first  $n$  FIBONACCI NUMBERS: 1, 11, 112, 1123, 11235, ... (Sloane's A019523; Marimutha 1997),
3. The smallest number that is the sum of squares of two distinct earlier terms: 1, 2, 5, 26, 29, 677, ... (Sloane's A008318, Bencze 1997),
4. The smallest number that is the sum of squares of any number of distinct earlier terms: 1, 1, 2, 4, 5, 6, 16, 17, ... (Sloane's A008319, Bencze 1997),
5. The smallest number that is *not* the sum of squares of two distinct earlier terms: 1, 2, 3, 4, 6, 7, 8, 9, 11, ... (Sloane's A008320, Bencze 1997),
6. The smallest number that is *not* the sum of squares of any number of distinct earlier terms: 1, 2, 3, 6, 7, 8, 11, ... (Sloane's A008321, Bencze 1997),

7. The smallest number that is a sum of cubes of *two* distinct earlier terms: 1, 2, 9, 730, 737, ... (Sloane's A008322, Bencze 1997),
8. The smallest number that is a sum of cubes of any number of distinct earlier terms: 1, 1, 2, 8, 9, 512, 513, 514, ... (Sloane's A008323, Bencze 1997),
9. The smallest number that is *not* a sum of cubes of *two* of distinct earlier terms: 1, 2, 3, 4, 5, 6, 7, 8, 10, ... (Sloane's A008380, Bencze 1997),
10. The smallest number that is *not* a sum of cubes of any number of distinct earlier terms: 1, 2, 3, 4, 5, 6, 7, 10, 11, ... (Sloane's A008381, Bencze 1997),
11. The number of PARTITIONS of a number  $n = 1, 2, \dots$  into SQUARE NUMBERS: 1, 1, 1, 1, 2, 2, 2, 2, 3, 4, 4, 4, 5, 6, 6, 6, 8, 9, 10, 10, 12, 13, ... (Sloane's A001156, Iacobescu 1997),
12. The number of PARTITIONS of a number  $n = 1, 2, \dots$  into CUBIC NUMBERS: 1, 1, 1, 1, 1, 1, 1, 1, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 3, 3, 3, ... (Sloane's A003108, Iacobescu 1997),
13. Two copies of the first  $n$  POSITIVE integers: 11, 1212, 123123, 12341234, ... (Sloane's A019524, Iacobescu 1997),
14. Numbers written in base of triangular numbers: 1, 2, 10, 11, 12, 100, 101, 102, 110, 1000, 1001, 1002, ... (Sloane's A000462, Iacobescu 1997),
15. Numbers written in base of double factorial numbers: 1, 10, 100, 101, 110, 200, 201, 1000, 1001, 1010, ... (Sloane's A019513, Iacobescu 1997),
16. Sequences starting with terms  $\{a_1, a_2\}$  which contain no three-term arithmetic progressions starting with  $\{1, 2\}$ : 1, 2, 4, 5, 10, 11, 13, 14, 28, ... (Sloane's A033155, Iacobescu 1997, Mudge 1997, Weisstein),
17. Numbers of the form  $(n!)^2 + 1$ : 2, 5, 37, 577, 14401, 518401, 25401601, 1625702401, 131681894401, ... (Sloane's A020549, Iacobescu 1997),
18. Numbers of the form  $(n!)^3 + 1$ : 2, 9, 217, 13825, 1728001, 373248001, 128024064001, ... (Sloane's A019514, Iacobescu 1997),
19. Numbers of the form  $1 + 1!2!3! \cdots n!$ : 2, 3, 13, 289, 34561, 24883201, 125411328001, 5056584744960001, ... (Sloane's A019515, Iacobescu 1997),
20. Sequences starting with terms  $\{a_1, a_2\}$  which contain no three-term geometric progressions starting with  $\{1, 2\}$ : 1, 2, 3, 5, 6, 7, 8, 10, 11, 13, 14, 15, 16, ... (Sloane's A000452, Iacobescu 1997),
21. Numbers repeating the digit 1  $p_n$  times, where  $p_n$  is the  $n$ th prime: 11, 111, 11111, 1111111, ... (Sloane's A031974, Iacobescu 1997). These are a subset of the REPUNITS,
22. Integers with all 2s, 3s, 5s, and 7s (prime digits) removed: 1, 4, 6, 8, 9, 10, 11, 1, 1, 14, 1, 16, 1, 18, 19, 0, ... (Sloane's A019516, Iacobescu 1997),
23. Integers with all 0s, 1s, 4s, and 9s (square digits) removed: 2, 3, 5, 6, 7, 8, 2, 3, 5, 6, 7, 8, 2, 2, 22, 23, ... (Sloane's A031976, Iacobescu 1997),
24. (Smarandache-Fibonacci triples) Integers  $n$  such that  $S(n) = S(n-1) + S(n-2)$ , where  $S(k)$  is the SMARANDACHE FUNCTION: 3, 11, 121, 4902, 26245, ... (Sloane's A015047; Aschbacher and Mudge 1995; Ibstedt 1997, pp. 19–23; Begay 1997). The largest known is 19,448,047,080,036,
25. (Smarandache-Radu triplets) Integers  $n$  such that there are no primes between the smaller and larger of  $S(n)$  and  $S(n+1)$ : 224, 2057, 265225, ... (Sloane's A015048; Radu 1994/1995, Begay 1997, Ibstedt 1997). The largest known is 270,329,975,921, 205,253,634,707,051,822,848,570,391,313,
26. (Smarandache crescendo sequence): Integers obtained by concatenating strings of the first  $n+1$  integers for  $n = 0, 1, 2, \dots$ : 1, 1, 2, 1, 2, 3, 1, 2, 3, 4, ... (Sloane's A002260; Brown 1997, Brown and Castillo 1997). The  $n$ th term is given by  $n - m(m+1)/2 + 1$ , where  $m = \lfloor (\sqrt{8n+1} - 1)/2 \rfloor$ , with  $\lfloor x \rfloor$  the FLOOR FUNCTION (Hamel 1997),
27. (Smarandache descrescendo sequence): Integers obtained by concatenating strings of the first  $n$  integers for  $n = \dots, 2, 1$ : 1, 2, 1, 3, 2, 1, 4, 3, 2, 1, ... (Sloane's A004736; Smarandache 1997, Brown 1997),
28. (Smarandache crescendo pyramidal sequence): Integers obtained by concatenating strings of rising and falling integers: 1, 1, 2, 1, 1, 2, 3, 2, 1, 1, 2, 3, 4, 3, 2, 1, ... (Sloane's A004737; Brown 1997, Brown and Castillo 1997, Smarandache 1997),
29. (Smarandache descrescendo pyramidal sequence): Integers obtained by concatenating strings of falling and rising integers: 1, 2, 1, 2, 3, 2, 1, 2, 3, 4, 3, 2, 1, 2, 3, 4, ... (Brown 1997),
30. (Smarandache crescendo symmetric sequence): 1, 1, 1, 2, 2, 1, 1, 2, 3, 3, 2, 1, ... (Sloane's A004739, Brown 1997, Smarandache 1997),
31. (Smarandache descrescendo symmetric sequence): 1, 1, 2, 1, 1, 2, 3, 2, 1, 1, 2, 3, ... (Sloane's A004740; Brown 1997, Smarandache 1997),
32. (Smarandache permutation sequence): Numbers obtained by concatenating sequences of increasing length of increasing ODD NUMBERS and decreasing EVEN NUMBERS: 1, 2, 1, 3, 4, 2, 1, 3, 5, 6, 4, 2, ... (Sloane's A004741; Brown 1997, Brown and Castillo 1997),
33. (Smarandache pierced chain sequence): Numbers of the form  $c(n) = 101 \underbrace{0101}_n$  for  $n = 0, 1, \dots$ : 101, 1010101, 10101010101, ... (Sloane's A031982; Ashbacher 1997). In addition,  $c(n)/101$  contains no PRIMES (Ashbacher 1997),

34. (Smarandache symmetric sequence): 1, 11, 121, 1221, 12321, 123321, ... (Sloane's A007907; Smarandache 1993, Dumitrescu and Seleacu 1994, sequence 3; Mudge 1995),
35. (Smarandache square-digital sequence): square numbers all of whose digits are also squares: 1, 4, 9, 49, 100, 144, ... (Sloane's A019544; Mudge 1997),
36. (Square-digits): numbers composed of digits which are squares: 1, 4, 9, 10, 14, 19, 40, 41, 44, 49, ... (Sloane's A066030),
37. (Smarandache square-digital sequence): square-digit numbers which are themselves squares: 1, 4, 9, 49, 100, 144, ... (Sloane's A019544; Mudge 1997),
38. (Cube-digits): numbers composed of digits which are cubes: 1, 4, 10, 11, 14, 40, 41, 44, 100, 101, ... (Sloane's A046031),
39. (Smarandache cube-digital sequence): cube-digit numbers which are themselves cubes: 1, 8, 1000, 8000, 1000000, ... (Sloane's A019545; Mudge 1997),
40. (Prime-digits): numbers composed of digits which are primes: 2, 3, 5, 7, 22, 23, 25, 27, 32, 33, 35, ... (Sloane's A046034),
41. (Smarandache prime-digital sequence): prime-digit numbers which are themselves prime: 2, 3, 5, 7, 23, 37, 53, ... (Smith 1996, Mudge 1997).

#### Smarandache-Wagstaff Function

Given the sum-of-FACTORIALS function

$$\Sigma(n) = \sum_{k=1}^n k!,$$

$SW(p)$  is the smallest integer for  $p$  PRIME such that  $\Sigma[SW(p)]$  is divisible by  $p$ . The first few known values are 2, 4, 5, 12, 19, 24, 32, 19, 20, 20, 20, 7, 57, 6, ... for  $p = 3, 11, 17, 23, 29, 37, 41, 43, 53, 67, 73, 79, 97, \dots$ . The values for 5, 7, 13, 31, ..., if they are finite, must be very large.

#### Smith Brothers

Consecutive SMITH NUMBERS. The first two brothers are (728, 729) and (2964, 2965).

see also SMITH NUMBER

#### Smith Conjecture

The set of fixed points which do not move as a knot is transformed into itself is not a KNOT. The conjecture was proved in 1978.

**Smith's Markov Process Theorem**

Consider

$$P_2(y_1, t | y_3, t_3) = \int P_2(y_1, t_1 | y_2, t_1) P_3(y_1, t_1; y_2, t_2 | y_3, t_3) dy_2. \quad (1)$$

If the probability distribution is governed by a MARKOV PROCESS, then

$$\begin{aligned} P_3(y_1, t_1; y_2, t_2 | y_3, t_3) &= P_2(y_2, t_2 | y_3, t_3) \\ &= P_2(y_2 | y_3, t_3 - t_2). \end{aligned} \quad (2)$$

Assuming no time dependence, so  $t_1 \equiv 0$ ,

$$P_2(y_1 | y_3, t_3) = \int P_2(y_1 | y_2, t_2) P_2(y_2 | y_3, t_3 - t_2) dy_2. \quad (3)$$

see also MARKOV PROCESS

**Smith's Network Theorem**

In a NETWORK with three EDGES at each VERTEX, the number of HAMILTONIAN CIRCUITS through a specified EDGE is 0 or EVEN.

see also EDGE (GRAPH), HAMILTONIAN CIRCUIT, NETWORK

**Smith Normal Form**

A form for INTEGER matrices.

**Smith Number**

A COMPOSITE NUMBER the SUM of whose DIGITS is the sum of the DIGITS of its PRIME factors (excluding 1). (The PRIMES are excluded since they trivially satisfy this condition). One example of a Smith number is the BEAST NUMBER

$$666 = 2 \cdot 3 \cdot 3 \cdot 37,$$

since

$$6 + 6 + 6 = 2 + 3 + 3 + (3 + 7) = 18.$$

Another Smith number is

$$4937775 = 3 \cdot 5 \cdot 5 \cdot 65837,$$

since

$$4 + 9 + 3 + 7 + 7 + 7 + 5 = 3 + 5 + 5 + (6 + 5 + 8 + 3 + 7) = 42.$$

The first few Smith numbers are 4, 22, 27, 58, 85, 94, 121, 166, 202, 265, 274, 319, 346, ... (Sloane's A006753). There are 360 Smith numbers less than  $10^4$  and  $29,928 \leq 10^6$ . McDaniel (1987a) showed that an infinite number exist.

A generalized  $k$ -Smith number can also be defined as a number  $m$  satisfying  $S_p(m) = kS(m)$ , where  $S_p$  is the sum of prime factors and  $S$  is the sum of digits. There are 47 1-Smith numbers, 21 2-Smith numbers, three 3-Smith numbers, and one 7-Smith, 9-Smith, and 14-Smith number  $< 1000$ .

A Smith number can be constructed from every factored REPUNIT  $R_n$ . The largest known Smith number is

$$9 \times R_{1031}(10^{4594} + 3 \times 10^{2297} + 1)^{1476} \times 10^{3913210}.$$

**Smooth Manifold**

Another word for a  $C^\infty$  (infinitely differentiable) MANIFOLD. A smooth manifold is a TOPOLOGICAL MANIFOLD together with its "functional structure" (Bredon 1995) and so differs from a TOPOLOGICAL MANIFOLD because the notion of differentiability exists on it. Every smooth manifold is a TOPOLOGICAL MANIFOLD, but not necessarily vice versa. (The first nonsmooth TOPOLOGICAL MANIFOLD occurs in 4-D.) In 1959, Milnor showed that a 7-D HYPERSPHERE can be made into a smooth manifold in 28 ways.

see also DIFFERENTIABLE MANIFOLD, HYPERSPHERE, MANIFOLD, TOPOLOGICAL MANIFOLD

**References**

- Bredon, G. E. *Topology & Geometry.* New York: Springer-Verlag, p. 69, 1995.

**Smooth Number**

An INTEGER is  $k$ -smooth if it has no PRIME FACTORS  $> k$ . The probability that a random POSITIVE INTEGER  $\leq n$  is  $k$ -smooth is  $\psi(n, k)/n$ , where  $\psi(n, k)$  is the number of  $k$ -smooth numbers  $\leq n$ . This fact is important in

application of Kraitichik's extension of FERMAT'S FACTORIZATION METHOD because it is related to the number of random numbers which must be examined to find a suitable subset whose product is a square.

Since about  $\pi(k)$   $k$ -smooth numbers must be found (where  $\pi(k)$  is the PRIME COUNTING FUNCTION), the number of random numbers which must be examined is about  $\pi(k)n/\psi(n, k)$ . But because it takes about  $\pi(k)$  steps to determine if a number is  $k$ -smooth using TRIAL DIVISION, the expected number of steps needed to find a subset of numbers whose product is a square is  $\sim [\pi(k)]^2 n/\psi(n, k)$  (Pomerance 1996). Canfield *et al.* (1983) showed that this function is minimized when

$$k \sim \exp(\tfrac{1}{2} \sqrt{\ln n \ln \ln n})$$

and that the minimum value is about

$$\exp(2\sqrt{\ln n \ln \ln n}).$$

In the CONTINUED FRACTION FACTORIZATION ALGORITHM,  $n$  can be taken as  $2\sqrt{n}$ , but in FERMAT'S FACTORIZATION METHOD, it is  $n^{1/2+\epsilon}$ .  $k$  is an estimate for the largest PRIME in the FACTOR BASE (Pomerance 1996).

#### Smooth Surface

A surface PARAMETERIZED in variables  $u$  and  $v$  is called smooth if the TANGENT VECTORS in the  $u$  and  $v$  directions satisfy

$$\mathbf{T}_u \times \mathbf{T}_v \neq \mathbf{0},$$

where  $\mathbf{A} \times \mathbf{B}$  is a CROSS PRODUCT.

#### Snake

A simple circuit in the  $d$ -HYPERCUBE which has no chords (i.e., for which all snake edges are edges of the HYPERCUBE). Klee (1970) asked for the maximum length  $s(d)$  of a  $d$ -snake. Klee (1970) gave the bounds

$$\frac{7}{4(d-1)} \leq \frac{s(d)}{2^d} \leq \frac{1}{2} - \frac{1-12 \dots 2^{-d}}{7d(d-1)^2+2} \quad (1)$$

for  $d \geq 6$  (Danzon and Klee 1967, Douglas 1969), as well as numerous references. Abbott and Katchalski (1988) show

$$s(d) \geq 77 \cdot 2^{d-8}, \quad (2)$$

and Snevily (1994) showed that

$$s(d) \leq 2^{n-1} \left(1 - \frac{1}{20n-41}\right) \quad (3)$$

for  $n \leq 12$ , and conjectured

$$s(d) \leq 3 \cdot 2^{n-3} + 2 \quad (4)$$

for  $n \leq 5$ . The first few values for  $s(d)$  for  $d = 1, 2, \dots$ , are 2, 4, 6, 8, 14, 26, ... (Sloane's A000937).

#### Snake Eyes

A roll of two 1s (the lowest roll possible) on a pair of six-sided DICE. The probability of rolling snake eyes is  $1/36$ , or  $2.777\dots\%$ .

see also BOXCARS

#### Snake Oil Method

The expansion of the two sides of a sum equality in terms of POLYNOMIALS in  $x^m$  and  $y^k$ , followed by closed form summation in terms of  $x$  and  $y$ . For an example of the technique, see Bloom (1995).

**Snedecor's F-Distribution**

If a random variable  $X$  has a CHI-SQUARED DISTRIBUTION with  $m$  degrees of freedom ( $\chi_m^2$ ) and a random variable  $Y$  has a CHI-SQUARED DISTRIBUTION with  $n$  degrees of freedom ( $\chi_n^2$ ), and  $X$  and  $Y$  are independent, then

$$F \equiv \frac{X/m}{Y/n} \quad (1)$$

is distributed as Snedecor's  $F$ -distribution with  $m$  and  $n$  degrees of freedom

$$f(F(m, n)) = \frac{\Gamma\left(\frac{m+n}{2}\right) \left(\frac{m}{n}\right)^{m/2} F^{(m-2)/2}}{\Gamma\left(\frac{m}{2}\right) \Gamma\left(\frac{n}{2}\right) \left(1 + \frac{m}{n}F\right)^{(m+n)/2}} \quad (2)$$

for  $0 < F < \infty$ . The MOMENTS about 0 are

$$\mu'_1 = \frac{n}{n-2} \quad (3)$$

$$\mu'_2 = \frac{n^2(m+2)}{m(n-2)(n-4)} \quad (4)$$

$$\mu'_3 = \frac{n^3(m+2)(m+4)}{m^2(n-2)(n-4)(n-6)} \quad (5)$$

$$\mu'_4 = \frac{n^4(m+2)(m+4)(m+6)}{m^3(n-2)(n-4)(n-6)(n-8)}, \quad (6)$$

so the MOMENTS about the MEAN are given by

$$\mu_2 = \frac{2n^2(m+n-2)}{m(n-2)^2(n-4)} \quad (7)$$

$$\mu_3 = \frac{8n^3(m+n-2)(2m+n-2)}{m^2(n-2)^3(n-4)(n-6)} \quad (8)$$

$$\mu_4 = \frac{12n^4(m+n-2)}{m^3(n-2)^4(n-4)(n-6)(n-8)} g(m, n), \quad (9)$$

where

$$g(m, n) = mn^2 + 4n^2 + m^2n + 8mn - 16n + 10m^2 - 20m + 16, \quad (10)$$

and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \mu'_1 = \frac{n}{n-2} \quad (11)$$

$$\sigma^2 = \frac{2n^2(m+n-2)}{m(n-2)^2(n-4)} \quad (12)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = 2\sqrt{\frac{2(n-4)}{m(m+n-2)}} \frac{2m+n-2}{n-6} \quad (13)$$

$$\begin{aligned} \gamma_2 &= \frac{\mu_4}{\sigma^4} - 3 \\ &= \frac{12h(m, n)}{m(m+n-2)(n-6)(n-8)}, \end{aligned} \quad (14)$$

where

$$h(m, n) \equiv n^3 + 5mn^2 - 8n^2 + 5m^2n - 32mn + 20n - 22m^2 + 44m - 16. \quad (15)$$

Letting

$$w \equiv \frac{\frac{mF}{n}}{1 + \frac{mF}{n}} \quad (16)$$

gives a BETA DISTRIBUTION.

## Snub Dodecadodecahedron 1667

The coordinates of the VERTICES may be found by solving the set of four equations

$$1 + x_2^2 + z_1^2 = 4$$

$$(x_2 - 1)^2 + (z_3 - z_1)^2 = 4$$

$$x_2^2 + (z_3 - z_2)^2 = 4$$

$$x_2^2 + x_2^2 + (z_2 - z_1)^2 = 4$$

for the four unknowns  $x_2$ ,  $z_1$ ,  $z_2$ , and  $z_3$ . Numerically,

$$x_2 = 1.28917$$

$$z_1 = 1.15674$$

$$z_2 = 1.97898$$

$$z_3 = 3.13572.$$

The analytic solution requires solving the CUBIC EQUATION and gives

$$x_2 = 1 - 7 \cdot 2^{-2/3} (1 - i\sqrt{3})\alpha^{-1} - \frac{1}{6} \cdot 2^{-1/3} (1 + i\sqrt{3})\alpha$$

$$z_1 = \frac{1}{3} \cdot 2^{-1/2} [-48 + 6\beta(1 + i\sqrt{3}) + \beta^2(1 - i\sqrt{3})$$

$$+ 147\beta\gamma(\sqrt{3} - i) + 42\beta^2\gamma(\sqrt{3} + i)]^{1/2},$$

where

$$\alpha \equiv (12i\sqrt{237} - 54)^{1/3}$$

$$\beta \equiv 3^{1/3} (2i\sqrt{237} - 9)^{1/3}$$

$$\gamma \equiv (9i + 2\sqrt{237})^{-1}.$$

## Snub Dodecadodecahedron

The UNIFORM POLYHEDRON  $U_{40}$  whose DUAL POLYHEDRON is the MEDIAL PENTAGONAL HEXECONTAHEDRON. It has WYTHOFF SYMBOL  $|2 \frac{5}{2} 5$ . Its faces are  $12\{\frac{5}{2}\} + 60\{3\} + 12\{5\}$ . It has CIRCUMRADIUS for  $a = 1$  of

$$R = 1.27443994.$$

**Sociable Numbers**

Numbers which result in a periodic **ALIQUOT SEQUENCE**. If the period is 1, the number is called a **PERFECT NUMBER**. If the period is 2, the two numbers are called an **AMICABLE PAIR**. If the period is  $t \geq 3$ , the number is called sociable of order  $t$ . Only two sociable numbers were known prior to 1970, the sets of orders 5 and 28 discovered by Poulet (1918). In 1970, Cohen discovered nine groups of order 4.

The table below summarizes the number of sociable cycles known as given in the compilation by Moews (1995).

order	known
3	0
4	38
5	1
6	2
8	2
9	1
28	1

### Social Choice Theory

The theory of analyzing a decision between a collection of alternatives made by a collection of  $n$  voters with separate opinions. Any choice for the entire group should reflect the desires of the individual voters to the extent possible.

Fair choice procedures usually satisfy ANONYMITY (invariance under permutation of voters), DUALITY (each alternative receives equal weight for a single vote), and MONOTONICITY (a change favorable for  $X$  does not hurt  $X$ ). Simple majority vote is anonymous, dual, and monotone. MAY'S THEOREM states a stronger result.

see also ANONYMOUS, DUAL VOTING, MAY'S THEOREM, MONOTONIC VOTING, VOTING

### Soddy Circles

Given three distinct points  $A$ ,  $B$ , and  $C$ , let three CIRCLES be drawn, one centered about each point and each one tangent to the other two. Call the RADII  $r_i$  ( $r_3 = a'$ ,  $r_1 = b'$ ,  $r_2 = c'$ ). Then the CIRCLES satisfy

$$a' + b' = c \quad (1)$$

$$a' + c' = b \quad (2)$$

$$b' + c' = a, \quad (3)$$

as shown in the diagram below.

Solving for the RADII then gives

$$a' = \frac{1}{2}(b + c - a) \quad (4)$$

$$b' = \frac{1}{2}(a + c - b) \quad (5)$$

$$c' = \frac{1}{2}(a + b - c). \quad (6)$$

The above TRIANGLE has sides  $a$ ,  $b$ , and  $c$ , and SEMIPERIMETER

$$s \equiv \frac{1}{2}(a + b + c). \quad (7)$$

Plugging in,

$$2s = (a' + b') + (a' + c') + (b' + c') = 2(a' + b' + c'), \quad (8)$$

giving

$$a' + b' + c' = s. \quad (9)$$

In addition,

$$a = b' + c' = a' + b' + c' - a' = s - a'. \quad (10)$$

Switching  $a$  and  $a'$  to opposite sides of the equation and noting that the above argument applies equally well to  $b'$  and  $c'$  then gives

$$a' = s - a \quad (11)$$

$$b' = s - b \quad (12)$$

$$c' = s - c. \quad (13)$$

As can be seen from the first figure, there exist exactly two nonintersecting CIRCLES which are TANGENT to all three CIRCLES. These are called the inner and outer Soddy circles ( $S$  and  $S'$ , respectively), and their centers are called the inner and outer SODDY POINTS.

The inner Soddy circle is the solution to the FOUR COINS PROBLEM. The center  $S$  of the inner Soddy circle is the EQUAL DETOUR POINT, and the center of the outer Soddy circle  $S'$  is the ISOPERIMETRIC POINT (Kimberling 1994).

Frederick Soddy (1936) gave the FORMULA for finding the RADII of the Soddy circles ( $r_4$ ) given the RADII  $r_i$  ( $i = 1, 2, 3$ ) of the other three. The relationship is

$$2(\epsilon_1^2 + \epsilon_2^2 + \epsilon_3^2 + \epsilon_4^2) = (\epsilon_1 + \epsilon_2 + \epsilon_3 + \epsilon_4)^2, \quad (14)$$

where  $\epsilon_i \equiv \pm \kappa_i = \pm 1/r_i$  are the so-called BENDS, defined as the signed CURVATURES of the CIRCLES. If the contacts are all external, the signs are all taken as POSITIVE, whereas if one circle surrounds the other three, the sign of this circle is taken as NEGATIVE (Coxeter 1969). Using the QUADRATIC FORMULA to solve for  $\epsilon_4$ , expressing in terms of radii instead of curvatures, and simplifying gives

$$r_4^{\pm} = \frac{r_1 r_2 r_3}{r_2 r_3 + r_1(r_2 + r_3) \pm 2\sqrt{r_1 r_2 r_3(r_1 + r_2 + r_3)}}. \quad (15)$$

Here, the NEGATIVE solution corresponds to the outer Soddy circle and the POSITIVE one to the inner Soddy circle.

This FORMULA is called the DESCARTES CIRCLE THEOREM since it was known to Descartes. However, Soddy also extended it to SPHERES. Gosper has further extended the result to  $n + 2$  mutually tangent  $n$ -D HYPERSPHERES, whose CURVATURES satisfy

$$\left( \sum_{i=0}^{n+1} \kappa_i \right)^2 - n \sum_{i=0}^{n+1} \kappa_i^2 = 0. \quad (16)$$

Solving for  $\kappa_{n+1}$  gives

$$\kappa_{n+1} = \frac{\sqrt{n} \sqrt{\left( \sum_{i=0}^n \kappa_i \right)^2 - (n-1) \sum_{i=0}^n \kappa_i^2} + \sum_{i=0}^n \kappa_i}{n-1}. \quad (17)$$

For (at least)  $n = 2$  and 3, the RADICAL equals

$$f(n)V\kappa_0\kappa_1 \cdots \kappa_n, \quad (18)$$

where  $V$  is the CONTENT of the SIMPLEX whose vertices are the centers of the  $n + 1$  independent HYPERSPHERES. The RADICAND can also become NEGATIVE, yielding an IMAGINARY  $\kappa_{n+1}$ . For  $n = 3$ , this corresponds to a sphere touching three large bowling balls and a small BB, all mutually tangent, which is an impossibility.

Bellew has derived a generalization applicable to a CIRCLE surrounded by  $n$  CIRCLES which are, in turn, circumscribed by another CIRCLE. The relationship is

$$\begin{aligned} [n(c_n - 1)^2 + 1] \sum_{i=1}^n \kappa_i^2 + n(3nc_n^2 - 2n - 6)c_n^2(c_n - 1)^2 = \\ \frac{1}{[n(c_n - 1) + 1]^2} \times \{n(c_n - 1)^2 + 1\} \sum_{i=1}^n \kappa_i \\ + nc_n(c_n - 1)(nc_n^2 + (3 - n)c_n - 4)\}, \end{aligned} \quad (19)$$

where

$$c_n \equiv \csc\left(\frac{\pi}{n}\right). \quad (20)$$

For  $n = 3$ , this simplifies to the Soddy formula.

### Soddy's Hexlet

see HEXLET

### Soddy Line

A LINE on which the INCENTER  $I$ , GERGONNE POINT  $Ge$ , and inner and outer SODDY POINTS  $S$  and  $S'$  lie (the latter two of which are the EQUAL DETOUR POINT and the ISOPERIMETRIC POINT). The Soddy line can be given parametrically by

$$I + \lambda Ge,$$

where  $\lambda$  is a parameter. It is also given by

$$\sum (f - e)\alpha = 0,$$

where cyclic permutations of  $d$ ,  $e$ , and  $f$  are taken and the sum is over TRILINEAR COORDINATES  $\alpha$ ,  $\beta$ , and  $\gamma$ .

$\lambda$	Center
-4	outer Griffiths point $Gr'$
-2	outer Oldknow point $Ol'$
$-\frac{4}{3}$	outer Rigby point $Ri'$
-1	outer Soddy center $S'$
0	incenter $I$
1	inner Soddy center $S$
$\frac{4}{3}$	inner Rigby point $Ri$
2	inner Oldknow point $Ol$
4	inner Griffiths point $Gr$
$\infty$	Gergonne point

$S'$ ,  $I$ ,  $S$ , and  $Ge$  are COLLINEAR and form a HARMONIC RANGE (Vandeghen 1964, Oldknow 1996). There are a total of 22 HARMONIC RANGES for sets of four points out of these 10 (Oldknow 1996).

The Soddy line intersects the EULER LINE in the DE LONGCHAMPS POINT, and the GERGONNE LINE in the FLETCHER POINT.

The GEOMETRY of the LIE GROUP  $R$  SEMIDIRECT PRODUCT with  $R^2$ , where  $R$  acts on  $R^2$  by  $(t, (x, y)) \rightarrow (e^t x, e^{-t} y)$ .

see also THURSTON'S GEOMETRIZATION CONJECTURE

### Soldner's Constant

Consider the following formulation of the PRIME NUMBER THEOREM,

$$\pi(x) = \sum \frac{\mu(m)}{m} \int_c^x \frac{dt}{\ln t},$$

where  $\mu(m)$  is the MÖBIUS FUNCTION and  $c$  (sometimes also denoted  $\mu$ ) is Soldner's constant. Ramanujan found  $c = 1.45136380\dots$  (Hardy 1969, Le Lionnais 1983, Berndt 1994). Soldner (cited in Nielsen 1965) derived the correct value of  $c$  as  $1.4513692346\dots$ , where  $c$  is the root of

$$L(x) = \lim_{\epsilon \rightarrow 0} \int_0^{1-\epsilon} \frac{dt}{\ln t} + \int_{1+\epsilon}^{\infty} \frac{dt}{\ln t}$$

(Le Lionnais 1983).

### Solenoidal Field

A solenoidal VECTOR FIELD satisfies

$$\nabla \cdot \mathbf{B} = 0 \quad (1)$$

for every VECTOR  $\mathbf{B}$ , where  $\nabla \cdot \mathbf{B}$  is the DIVERGENCE. If this condition is satisfied, there exists a vector  $\mathbf{A}$ , known as the VECTOR POTENTIAL, such that

$$\mathbf{B} \equiv \nabla \times \mathbf{A}, \quad (2)$$

where  $\nabla \times \mathbf{A}$  is the CURL. This follows from the vector identity

$$\nabla \cdot \mathbf{B} = \nabla \cdot (\nabla \times \mathbf{A}) = 0. \quad (3)$$

If  $\mathbf{A}$  is an IRROTATIONAL FIELD, then

$$\mathbf{A} \times \mathbf{r} \quad (4)$$

is solenoidal. If  $\mathbf{u}$  and  $\mathbf{v}$  are irrotational, then

$$\mathbf{u} \times \mathbf{v} \quad (5)$$

is solenoidal. The quantity

$$(\nabla u) \times (\nabla v), \quad (6)$$

where  $\nabla u$  is the GRADIENT, is always solenoidal. For a function  $\phi$  satisfying LAPLACE'S EQUATION

$$\nabla^2 \phi = 0, \quad (7)$$

it follows that  $\nabla \phi$  is solenoidal (and also IRROTATIONAL).

### Solid

A closed 3-D figure (which may, according to some terminology conventions, be self-intersecting). Among the simplest solids are the SPHERE, CUBE, CONE, CYLINDER, and more generally, the POLYHEDRA.

see also APPLE, ARCHIMEDEAN SOLID, CATALAN SOLID, CONE, CORK PLUG, CUBE, CUBOCTAHEDRON, CYLINDER, CYLINDRICAL HOOFF, CYLINDRICAL WEDGE, DODECAHEDRON, GEODESIC DOME, GREAT DODECAHEDRON, GREAT ICOSAHEDRON, GREAT RHOMBICOSIDODECAHEDRON (ARCHIMEDEAN), GREAT RHOMBICUBOCTAHEDRON (ARCHIMEDEAN), GREAT STELLATED DODECAHEDRON, ICOSAHEDRON, ICOSIDODECAHEDRON, JOHNSON SOLID, KEPLER-POINOT SOLID, LEMON, MÖBIUS STRIP, OCTAHEDRON, PLATONIC SOLID, POLYHEDRON, PSEUDOSPHERE, RHOMBICOSIDODECAHEDRON, RHOMBICUBOCTAHEDRON, SMALL STELLATED DODECAHEDRON, SNUB CUBE, SNUB DODECAHEDRON, SOLID OF REVOLUTION, SPHERE, STEINMETZ SOLID, STELLA OCTANGULA, SURFACE, TETRAHEDRON, TORUS, TRUNCATED CUBE, TRUNCATED DODECAHEDRON, TRUNCATED ICOSAHEDRON, TRUNCATED OCTAHEDRON, TRUNCATED TETRAHEDRON, UNIFORM POLYHEDRON, WULFF SHAPE

### Solid Angle

Defined as the SURFACE AREA  $\Omega$  of a UNIT SPHERE which is subtended by a given object  $S$ . Writing the SPHERICAL COORDINATES as  $\phi$  for the COLATITUDE (angle from the pole) and  $\theta$  for the LONGITUDE (azimuth),

$$\Omega \equiv A_{\text{projected}} = \iint_S \sin \phi \, d\theta \, d\phi.$$

Solid angle is measured in STERADIANS, and the solid angle corresponding to all of space being subtended is  $4\pi$  STERADIANS.

see also SPHERE, STERADIAN

### Solid Geometry

That portion of GEOMETRY dealing with SOLIDS, as opposed to PLANE GEOMETRY. Solid geometry is concerned with POLYHEDRA, SPHERES, 3-D SOLIDS, lines in 3-space, PLANES, and so on.

see also GEOMETRY, PLANE GEOMETRY, SPHERICAL GEOMETRY

### Solid Partition

Solid partitions are generalizations of PLANE PARTITIONS. MacMahon (1960) conjectured the GENERATING FUNCTION for the number of solid partitions was

$$f(z) = \frac{1}{(1-z)(1-z^2)^3(1-z^3)^6(1-z^4)^{10}\dots},$$

but this was subsequently shown to disagree at  $n = 6$  (Atkin *et al.* 1967). Knuth (1970) extended the tabulation of values, but was unable to find a correct generating function. The first few values are 1, 4, 10, 26, 59, 140, ... (Sloane's A000293).

### Solid of Revolution

To find the VOLUME of a solid of rotation by adding up a sequence of thin cylindrical shells, consider a region bounded above by  $y = f(x)$ , below by  $y = g(x)$ , on the left by the LINE  $x = a$ , and on the right by the LINE  $x = b$ . When the region is rotated about the  $y$ -AXIS, the resulting VOLUME is given by

$$V = 2\pi \int_a^b x[f(x) - g(x)] \, dx.$$

To find the volume of a solid of rotation by adding up a sequence of thin flat disks, consider a region bounded above by  $y = f(x)$ , below by  $y = g(x)$ , on the left by the LINE  $x = a$ , and on the right by the LINE  $x = b$ . When the region is rotated about the  $x$ -AXIS, the resulting VOLUME is

$$V = \pi \int_a^b \{[f(x)]^2 - [g(x)]^2\} dx.$$

see also SURFACE OF REVOLUTION, VOLUME

### Solidus

The diagonal slash "/" used to denote DIVISION for in-line equations such as  $a/b$ ,  $1/(x-1)^2$ , etc. The solidus is also called a DIAGONAL.

see also DIVISION, OBELUS

### Solitary Number

A number which does not have any FRIENDS. Solitary numbers include all PRIMES and POWERS of PRIMES. More generally, numbers for which  $(n, \sigma(n)) = 1$  are solitary, where  $(a, b)$  is the GREATEST COMMON DIVISOR of  $a$  and  $b$  and  $\sigma(n)$  is the DIVISOR FUNCTION. The first few solitary numbers are 1, 2, 3, 4, 5, 7, 8, 9, 11, 13, 16, 17, 19, 21, ... (Sloane's A014567).

### Solomon's Seal Knot

The (5,2) TORUS KNOT 05<sub>001</sub> with BRAID WORD  $\sigma_1^5$ .

### Solomon's Seal Lines

The 27 REAL or IMAGINARY straight LINES which lie on the general CUBIC SURFACE and the 45 triple tangent PLANES to the surface. All are related to the 28 BITANGENTS of the general QUARTIC CURVE.

Schoutte (1910) showed that the 27 lines can be put into a ONE-TO-ONE correspondence with the vertices of a particular POLYTOPE in 6-D space in such a manner that all incidence relations between the lines are mirrored in the connectivity of the POLYTOPE and conversely (Du Val 1931). A similar correspondence can be made between the 28 bitangents and a 7-D POLYTOPE (Coxeter 1928) and between the tritangent planes of the canonical curve of genus four and an 8-D POLYTOPE (Du Val 1933).

### Solomon's Seal Polygon

see HEXAGRAM

### Solvable Congruence

A CONGRUENCE that has a solution.

### Solvable Group

A solvable group is a group whose composition indices are all PRIME NUMBERS. Equivalently, a solvable is a GROUP having a "normal series" such that each "normal factor" is ABELIAN. The term solvable derives from this type of group's relationship to GALOIS'S THEOREM, namely that the SYMMETRIC GROUP  $S_n$  is insoluble for  $n \geq 5$  while it is solvable for  $n = 1, 2, 3$ , and 4. As a result, the POLYNOMIAL equations of degree  $\geq 5$  are not solvable using finite additions, multiplications, divisions, and root extractions.

Every FINITE GROUP of order  $< 60$ , every ABELIAN GROUP, and every SUBGROUP of a solvable group is solvable.

### Soma Cube

A solid DISSECTION puzzle invented by Piet Hein during a lecture on Quantum Mechanics by Werner Heisenberg. There are seven soma pieces composed of all the *irregular* face-joined cubes (POLYCUBES) with  $\leq 4$  cubes. The object is to assemble the pieces into a CUBE. There are 240 essentially distinct ways of doing so (Beeler *et al.* 1972, Berlekamp *et al.* 1982), as first enumerated one rainy afternoon in 1961 by J. H. Conway and Mike Guy.

A commercial version of the cube colors the pieces black, green, orange, white, red, and blue. When the 48 symmetries of the cube, three ways of assembling the black piece, and  $2^5$  ways of assembling the green, orange, white, red, and blue pieces are counted, the total number of solutions rises to 1,105,920.

### Somer-Lucas Pseudoprime

An ODD COMPOSITE NUMBER  $N$  is called a Somer-Lucas  $d$ -pseudoprime (with  $d \geq 1$ ) if there EXISTS a nondegenerate LUCAS SEQUENCE  $U(P, Q)$  with  $U_0 = 0$ ,  $U_1 = 1$ ,  $D = P^2 - 4Q$ , such that  $(N, D) = 1$  and the rank appearance of  $N$  in the sequence  $U(P, Q)$  is  $(1/a)(N - (D/N))$ , where  $(D/N)$  denotes the JACOBI SYMBOL.

### Sommerfeld's Formula

There are (at least) two equations known as Sommerfeld's formula. The first is

$$J_\nu(z) = \frac{1}{2\pi} \int_{-\eta+i\infty}^{2\pi-\eta+i\infty} e^{iz \cos t} e^{i\nu(t-\pi/2)} dt,$$

where  $J_\nu(z)$  is a BESSEL FUNCTION OF THE FIRST KIND. The second states that under appropriate restrictions,

$$\int_0^\infty J_0(\tau r) e^{-|z|\sqrt{\tau^2 - k^2}} \frac{\tau d\tau}{\sqrt{\tau^2 - k^2}} = \frac{e^{ik\sqrt{\tau^2 + k^2}}}{\sqrt{\tau^2 + k^2}}.$$

see also WEYRICH'S FORMULA

#### References

### Somos Sequence

The Somos sequences are a set of related symmetrical RECURRENCE RELATIONS which, surprisingly, always give integers. The Somos sequence of order  $k$  is defined by

$$a_n = \frac{\sum_{j=1}^{\lfloor k/2 \rfloor} a_{n-j} a_{n-(k-j)}}{a_{n-k}},$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION and  $a_j = 1$  for  $j = 0, \dots, k-1$ . The 2- and 3-Somos sequences consist entirely of 1s. The  $k$ -Somos sequences for  $k = 4, 5, 6$ , and 7 are

$$a_n = \frac{a_{n-1}a_{n-3} + a_{n-2}^2}{a_{n-4}}$$

$$a_n = \frac{a_{n-1}a_{n-4} + a_{n-2}a_{n-3}}{a_{n-5}}$$

$$a_n = \frac{1}{a_{n-6}}[a_{n-1}a_{n-5} + a_{n-2}a_{n-4} + a_{n-3}^2]$$

$$a_n = \frac{1}{a_{n-7}}[a_{n-1}a_{n-6} + a_{n-2}a_{n-5} + a_{n-3}a_{n-4}],$$

giving 1, 1, 1, 2, 3, 7, 23, 59, 314, 1529, ... (Sloane's A006720), 1, 1, 1, 1, 2, 3, 5, 11, 37, 83, 274, 1217, ... (Sloane's A006721), 1, 1, 1, 1, 1, 3, 5, 9, 23, 75, 421, 1103, ... (Sloane's A006722), 1, 1, 1, 1, 1, 1, 3, 5, 9, 17, 41, 137, 769, ... (Sloane's A006723). Gale (1991) gives simple proofs of the integer-only property of the 4-Somos and 5-Somos sequences. Hickerson proved 6-Somos generates only integers using computer algebra, and empirical evidence suggests 7-Somos is also integer-only.

However, the  $k$ -Somos sequences for  $k \geq 8$  do not give integers. The values of  $n$  for which  $a_n$  first becomes nonintegral for the  $k$ -Somos sequence for  $k = 8, 9, \dots$  are 17, 19, 20, 22, 24, 27, 28, 30, 33, 34, 36, 39, 41, 42, 44, 46, 48, 51, 52, 55, 56, 58, 60, ... (Sloane's A030127). see also GÖBEL'S SEQUENCE, HERONIAN TRIANGLE

#### Sonine's Integral

$$J_m(x) = \frac{2x^{m-n}}{2^{m-n}\Gamma(m-n)} \int_0^1 J_n(xt)t^{n+1}(1-t^2)^{m-n-1} dt,$$

where  $J_m(x)$  is a BESSEL FUNCTION OF THE FIRST KIND and  $\Gamma(x)$  is the GAMMA FUNCTION.

see also HANKEL'S INTEGRAL, POISSON INTEGRAL

#### Sonine Polynomial

A polynomial which differs from the associated LAGUERRE POLYNOMIAL by only a normalization constant,

$$\begin{aligned} S_r^s(x) &= \frac{1}{s!} e^x x^{-r} \frac{d^s}{dx^s} (e^{-x} x^{r+s}) = \frac{(-1)^r}{(r+s)!} L_{r+s}^r(x) \\ &= \frac{x^s}{s!(r+s)!0!} - \frac{x^{s-1}}{(s-1)!(r+s-1)!1!} \\ &\quad + \frac{x^{s-2}}{(r-2)!(r+s-2)!2!} - \dots \\ &= \frac{1}{s!(r+s)!} x^{-(r+1)/2} e^{x/2} W_{s+r/2+1/2, r/2}(x), \end{aligned}$$

where  $W_{k,m}(z)$  is a WHITTAKER FUNCTION.

see also LAGUERRE POLYNOMIAL, WHITTAKER FUNCTION

#### Sonine-Schafheitlin Formula

$$\begin{aligned} \int_0^\infty J_\mu(at)J_\nu(bt)t^{-\lambda} dt \\ &= \frac{a^\mu \Gamma[(\mu + \nu - \lambda + 1)/2]}{2^\lambda b^{\mu-\lambda+1} \Gamma[(-\mu + \nu + \lambda + 1)/2] \Gamma(\mu + 1)} \\ &\times {}_2F_1((\mu + \nu - \lambda + 1)/2, (\mu - \nu - \lambda + 1)/2; \mu + 1; a^2/b^2), \end{aligned}$$

where  $\Re[\mu + \nu - \lambda + 1] > 0$ ,  $\Re[\lambda] > -1$ ,  $0 < a < b$ ,  $J_\nu(x)$  is a BESSEL FUNCTION OF THE FIRST KIND,  $\Gamma(x)$  is the GAMMA FUNCTION, and  ${}_2F_1(a, b; c; x)$  is a HYPERGEOMETRIC FUNCTION.

#### Sophie Germain Prime

A PRIME  $p$  is said to be a Sophie Germain prime if both  $p$  and  $2p + 1$  are PRIME. The first few Sophie Germain primes are 2, 3, 5, 11, 23, 29, 41, 53, 83, 89, 113, 131, ... (Sloane's A005384).

Around 1825, Sophie Germain proved that the first case of FERMAT'S LAST THEOREM is true for such primes, i.e., if  $p$  is a Sophie Germain prime, there do not exist INTEGERS  $x$ ,  $y$ , and  $z$  different from 0 and not multiples of  $p$  such that

$$x^p + y^p = z^p.$$

Sophie Germain primes  $p$  of the form  $p = k \cdot 2^n - 1$  (which makes  $2p + 1$  a PRIME) are COMPOSITE MERSENNE NUMBERS. Since the largest known COMPOSITE MERSENNE NUMBER is  $M_p$  with  $p = 39051 \times 2^{6001} - 1$ ,  $p$  is the largest known Sophie Germain prime.

see also CUNNINGHAM CHAIN, FERMAT'S LAST THEOREM, MERSENNE NUMBER, TWIN PRIMES

**Sorites Paradox**

Sorites paradoxes are a class of paradoxical arguments also known as little-by-little arguments. The name "sorites" derives from the Greek word *soros*, meaning "pile" or "heap". Sorites paradoxes are exemplified by the problem that a single grain of wheat does not comprise a heap, nor do two grains of wheat, three grains of wheat, etc. However, at some point, the collection of grains becomes large enough to be called a heap, but there is apparently no definite point where this occurs.

see also UNEXPECTED HANGING PARADOX

**Sort-Then-Add Sequence**

A sequence produced by sorting the digits of a number and adding them to the previous number. The algorithm terminates when a sorted number is obtained. For  $n = 1, 2, \dots$ , the algorithm terminates on 1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 11, 12, 13, 14, 15, 16, 17, 18, 19, 22, 33, ... (Sloane's A033862). The first few numbers not known to terminate are 316, 452, 697, 1376, 2743, 5090, ... (Sloane's A033861). The least numbers of sort-then-add persistence  $n = 1, 2, \dots$ , are 1, 10, 65, 64, 175, 98, 240, 325, 302, 387, 198, 180, 550, ... (Sloane's A033863).

**Sorting**

Sorting is the rearrangement of numbers (or other orderable objects) in a list into their correct lexicographic order. Alphabetization is therefore a form of sorting. Because of the extreme importance of sorting in almost all database applications, a great deal of effort has been expended in the creation and analysis of efficient sorting algorithms.

**Souslin Set**

The continuous image of a POLISH SPACE, also called an ANALYTIC SET.

see also ANALYTIC SET, POLISH SPACE

**Sous-Triple**

A MULTIPERFECT NUMBER  $P_4$ . 36 sous-triples are known, and these are believed to comprise all sous-triples.

see also MULTIPERFECT NUMBER, SOUS-DOUBLE

**Space**

The concept of a space is an extremely general and important mathematical construct. Members of the space obey certain addition properties. Spaces which have been investigated and found to be of interest are usually named after one or more of their investigators. This practice unfortunately leads to names which give very little insight into the relevant properties of a given space.

One of the most general type of mathematical spaces is the TOPOLOGICAL SPACE.

## Space Conic

see SKEW CONIC

## Space Curve

A curve which may pass through any region of 3-D space, as contrasted to a PLANE CURVE which must lie in a single PLANE. Von Staudt (1847) classified space curves geometrically by considering the curve

$$\phi : I \rightarrow \mathbb{R}^3 \quad (1)$$

at  $t_0 = 0$  and assuming that the parametric functions  $\phi_i(t)$  for  $i = 1, 2, 3$  are given by POWER SERIES which converge for small  $t$ . If the curve is contained in no PLANE for small  $t$ , then a coordinate transformation puts the parametric equations in the normal form

$$\phi_1(t) = t^{1+k_1} + \dots \quad (2)$$

$$\phi_2(t) = t^{2+k_1+k_2} + \dots \quad (3)$$

$$\phi_3(t) = t^{3+k_1+k_2+k_3} + \dots \quad (4)$$

for integers  $k_1, k_2, k_3 \geq 0$ , called the local numerical invariants.

## Space Diagonal

The LINE SEGMENT connecting opposite VERTICES (i.e., two VERTICES which do not share a common face) in a PARALLELEPIPED or other similar solid.

see also DIAGONAL (POLYGON), DIAGONAL (POLYHEDRON), EULER BRICK

## Space Distance

The maximum distance in 3-D can occur no more than  $2n - 2$  times. Also, there exists a fixed number  $c$  such that no distance determined by a set of  $n$  points in 3-D space occurs more than  $cn^{5/3}$  times. The maximum distance can occur no more than  $\lfloor \frac{1}{4}n^2 \rfloor$  times in 4-D, where  $\lfloor x \rfloor$  is the FLOOR FUNCTION.

**Space-Filling Polyhedron**

A space-filling polyhedron is a POLYHEDRON which can be used to generate a TESSELLATION of space. There exists one 16-sided space-filling POLYHEDRON, but it is unknown if this is the unique 16-sided space-filler. The CUBE, RHOMBIC DODECAHEDRON, and TRUNCATED OCTAHEDRON are space-fillers, as are the ELONGATED DODECAHEDRON and hexagonal PRISM. These five solids are all "primary" PARALLELOHEDRA (Coxeter 1973).

P. Schmitt discovered a nonconvex aperiodic polyhedral space-filler around 1990, and a convex POLYHEDRON known as the SCHMITT-CONWAY BIPRISM which fills space only aperiodically was found by J. H. Conway in 1993 (Eppstein).

**Space Groups**

The space groups in 2-D are called WALLPAPER GROUPS. In 3-D, the space groups are the symmetry GROUPS possible in a crystal lattice with the translation symmetry element. There are 230 space groups in  $\mathbb{R}^3$ , although 11 are MIRROR IMAGES of each other. They are listed by HERMANN-MAUGUIN SYMBOL in Cotton (1990).

**Span (Geometry)**

The largest possible distance between two points for a finite set of points.

see also JUNG'S THEOREM

**Span (Link)**

The span of an unoriented LINK diagram (also called the SPREAD) is the difference between the highest and lowest degrees of its BRACKET POLYNOMIAL. The span is a topological invariant of a knot. If a KNOT  $K$  has a reduced alternating projection of  $n$  crossings, then the span of  $K$  is  $4n$ .

see also LINK

**Span (Polynomial)**

The difference between the highest and lowest degrees of a POLYNOMIAL.

**Span (Set)**

For a SET  $S$ , the span is defined by  $\max S - \min S$ , where max is the MAXIMUM and min is the MINIMUM.

References

- Guy, R. K. *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, p. 207, 1994.

**Span (Vectors)**

The span of SUBSPACE generated by VECTORS  $\mathbf{v}_1$  and  $\mathbf{v}_2 \in \mathbb{V}$  is

$$\text{Span}(\mathbf{v}_1, \mathbf{v}_2) \equiv \{r\mathbf{v}_1 + s\mathbf{v}_2 : r, s \in \mathbb{R}\}.$$

**Sparse Matrix**

A MATRIX which has only a small number of NONZERO elements.

References

- Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Sparse Linear Systems." §2.7 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 63-82, 1992.

**Spearman Rank Correlation**

The Spearman rank correlation is defined by

$$r' \equiv \frac{\sum xy}{\sqrt{\sum x^2 \sum y^2}} = 1 - 6 \sum \frac{d^2}{N(N^2 - 1)}. \quad (1)$$

The VARIANCE, KURTOSIS, and higher order MOMENTS are

$$\sigma^2 = \frac{1}{N-1} \quad (2)$$

$$\gamma_2 = -\frac{114}{25N} - \frac{6}{5N^2} - \dots \quad (3)$$

$$\gamma_3 = \gamma_5 = \dots = 0. \quad (4)$$

Student was the first to obtain the VARIANCE. The Spearman rank correlation is an *R*-ESTIMATE.

Oxford, England: Clarendon Press, pp. xi-xii, 1985.

**Special Point**

A POINT which does not lie on at least one ORDINARY LINE.

see also ORDINARY POINT

**References**

Guy, R. K. "Unsolved Problems Come of Age." *Amer. Math. Monthly* **96**, 903-909, 1989.

**Special Series Theorem**

If the difference between the order and the dimension of a series is less than the GENUS (CURVE), then the series is special.

**References**

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 253, 1959.

**Special Unitary Group**

The special unitary group  $SU_n(q)$  is the set of  $n \times n$  UNITARY MATRICES with DETERMINANT +1 (having  $n^2 - 1$  independent parameters).  $SU(2)$  is HOMEOMORPHIC with the ORTHOGONAL GROUP  $O_3^+(2)$ . It is also called the UNITARY UNIMODULAR GROUP and is a LIE GROUP. The special unitary group can be represented by the MATRIX

$$U(a, b) = \begin{bmatrix} a & b \\ -b^* & a^* \end{bmatrix}, \quad (1)$$

where  $a^*a + b^*b = 1$  and  $a, b$  are the CAYLEY-KLEIN PARAMETERS. The special unitary group may also be represented by the MATRIX

$$U(\xi, \eta, \zeta) = \begin{bmatrix} e^{i\xi} \cos \eta & e^{i\zeta} \sin \eta \\ -e^{-i\xi} \sin \eta & e^{-i\xi} \cos \eta \end{bmatrix}, \quad (2)$$

or the matrices

$$U_x(\tfrac{1}{2}\phi) = \begin{bmatrix} \cos(\tfrac{1}{2}\phi) & i \sin(\tfrac{1}{2}\phi) \\ i \sin(\tfrac{1}{2}\phi) & \cos(\tfrac{1}{2}\phi) \end{bmatrix} \quad (3)$$

$$U_y(\tfrac{1}{2}\beta) = \begin{bmatrix} \cos(\tfrac{1}{2}\beta) & \sin(\tfrac{1}{2}\beta) \\ -\sin(\tfrac{1}{2}\beta) & \cos(\tfrac{1}{2}\beta) \end{bmatrix} \quad (4)$$

$$U_z(\xi) = \begin{bmatrix} e^{i\xi} & 0 \\ 0 & e^{-i\xi} \end{bmatrix}. \quad (5)$$

The order  $2j + 1$  representation is

$$U_{p,q}^{(j)}(\alpha, \beta, \gamma) = \sum_m \frac{(-1)^{m-q-p} \sqrt{(j+p)!(j-p)!(j+q)!(j-q)!}}{(j-p-m)!(j+q-m)!(m+p-q)!m!} \times e^{iq\alpha} \cos^{2j+q-p-2m}(\frac{1}{2}\beta) \sin^{p+2m-q}(\frac{1}{2}\beta) e^{ip\gamma}. \quad (6)$$

The summation is terminated by putting  $1/(-N)! = 0$ . The CHARACTER is given by

$$\chi^{(j)}(\alpha) = \begin{cases} 1 + 2 \cos \alpha + \dots + 2 \cos(j\alpha) \\ 2[\cos(\frac{1}{2}\alpha) + \cos(\frac{3}{2}\alpha) + \dots + \cos(j\alpha)] \end{cases}$$

$$= \begin{cases} \frac{\sin[(j+\frac{1}{2})\alpha]}{\sin(\frac{1}{2}\alpha)} & \text{for } j = 0, 1, 2, \dots \\ \frac{\sin[(j+\frac{1}{2})\alpha]}{\sin(\frac{1}{2}\alpha)} & \text{for } j = \frac{1}{2}, \frac{3}{2}, \dots \end{cases} \quad (7)$$

see also ORTHOGONAL GROUP, SPECIAL LINEAR GROUP, SPECIAL ORTHOGONAL GROUP

#### References

- Arfken, G. "Special Unitary Group,  $SU(2)$  and  $SU(2)-O_3^+$  Homomorphism." *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 253-259, 1985.
- Conway, J. H.; Curtis, R. T.; Norton, S. P.; Parker, R. A.; and Wilson, R. A. Oxford, England: Clarendon Press, p. x, 1985.

#### Species

A species of structures is a rule  $F$  which

1. Produces, for each finite set  $U$ , a finite set  $F[U]$ ,
2. Produces, for each bijection  $\sigma : U \rightarrow V$ , a function

$$F[\sigma] : F[U] \rightarrow F[V].$$

The functions  $F[\sigma]$  should further satisfy the following functorial properties:

1. For all bijections  $\sigma : U \rightarrow V$  and  $\tau : V \rightarrow W$ ,

$$F[\tau \circ \sigma] = F[\tau] \circ F[\sigma],$$

2. For the IDENTITY MAP  $\text{Id}_U : U \rightarrow U$ ,

$$F[\text{Id}] = \text{Id}_{F[U]}.$$

An element  $\sigma \in F[U]$  is called an  $F$ -structure on  $U$  (or a structure of species  $F$  on  $U$ ). The function  $F[\sigma]$  is called the transport of  $F$ -structures along  $\sigma$ .

#### Spectral Power Density

$$P_y(\nu) \equiv \lim_{T \rightarrow \infty} \frac{2}{T} \left| \int_{-T/2}^{T/2} [y(t) - \bar{y}] e^{-2\pi i \nu t} dt \right|^2,$$

so

$$\int_0^\infty P_y(\nu) d\nu = \lim_{T \rightarrow \infty} \frac{1}{T} \int_{-T/2}^{T/2} [y(t) - \bar{y}]^2 dt = \langle (y - \bar{y})^2 \rangle = \sigma_y^2.$$

see also POWER SPECTRUM

#### Spectral Radius

Let  $A$  be an  $n \times n$  MATRIX with COMPLEX or REAL elements with EIGENVALUES  $\lambda_1, \dots, \lambda_n$ . Then the spectral radius  $\rho(A)$  of  $A$  is

$$\rho(A) = \max_{1 \leq i \leq n} |\lambda_i|.$$

### Spectral Theorem

Let  $H$  be a HILBERT SPACE,  $B(H)$  the set of BOUNDED linear operators from  $H$  to itself, and  $\sigma(T)$  the SPECTRUM of  $T$ . Then if  $T \in B(H)$  and  $T$  is normal, there exists a unique resolution of the identity  $E$  on the Borel subsets of  $\sigma(T)$  which satisfies

$$T = \int_{\sigma(T)} \lambda dE(\lambda).$$

Furthermore, every projection  $E(\omega)$  COMMUTES with every  $S \in B(H)$  which COMMUTES with  $T$ .

#### References

Rudin, W. Theorem 12.23 in *Functional Analysis*, 2nd ed. New York: McGraw-Hill, 1991.

### Spectrum (Operator)

Let  $T$  be an OPERATOR on a HILBERT SPACE. The spectrum  $\sigma(T)$  of  $T$  is the set of  $\lambda$  such that  $(T - \lambda I)$  is not invertible on all of the HILBERT SPACE, where the  $\lambda$ s are COMPLEX NUMBERS and  $I$  is the IDENTITY OPERATOR. The definition can also be stated in terms of the resolvent of an operator

$$\rho(T) = \{\lambda : (T - \lambda I) \text{ is invertible}\},$$

and then the spectrum is defined to be the complement of  $\rho(T)$  in the COMPLEX PLANE. The reason for doing this is that it is easy to demonstrate that  $\rho(T)$  is an OPEN SET, which shows that the spectrum is closed.

see also HILBERT SPACE

### Spectrum Sequence

A spectrum sequence is a SEQUENCE formed by successive multiples of a REAL NUMBER  $a$  rounded down to the nearest INTEGER  $s_n = \lfloor na \rfloor$ . If  $a$  is IRRATIONAL, the spectrum is called a BEATTY SEQUENCE.

### Sphere

A sphere is defined as the set of all points in  $\mathbb{R}^3$  which are a distance  $r$  (the "RADIUS") from a given point (the "CENTER"). Twice the RADIUS is called the DIAMETER, and pairs of points on opposite sides of a DIAMETER are called ANTIPODES. The term "sphere" technically refers to the outer surface of a "BUBBLE," which is denoted  $\mathbb{S}^2$ . However, in common usage, the word *sphere* is also used to mean the UNION of a sphere and its INTERIOR (a "solid sphere"), where the INTERIOR is called a BALL. The SURFACE AREA of the sphere and VOLUME of the BALL of RADIUS  $r$  are given by

$$S = 4\pi r^2 \quad (1)$$

$$V = \frac{4}{3}\pi r^3 \quad (2)$$

(Beyer 1987, p. 130). In *On the Sphere and Cylinder* (ca. 225 BC), Archimedes became the first to derive these equations (although he expressed  $\pi$  in terms of the sphere's circular cross-section). The fact that

$$\frac{V_{\text{sphere}}}{V_{\text{circumscribed cylinder}} - V_{\text{sphere}}} = \frac{\frac{4}{3}}{2 - \frac{4}{3}} = \frac{\frac{4}{3}}{\frac{2}{3}} = 2 \quad (3)$$

was also known to Archimedes.

Any cross-section through a sphere is a CIRCLE (or, in the degenerate case where the slicing PLANE is tangent to the sphere, a point). The size of the CIRCLE is maximized when the PLANE defining the cross-section passes through a DIAMETER.

The equation of a sphere of RADIUS  $r$  is given in CARTESIAN COORDINATES by

$$x^2 + y^2 + z^2 = r^2, \quad (4)$$

which is a special case of the ELLIPSOID

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \quad (5)$$

and SPHEROID

$$\frac{x^2 + y^2}{a^2} + \frac{z^2}{c^2} = 1. \quad (6)$$

A sphere may also be specified in SPHERICAL COORDINATES by

$$x = \rho \cos \theta \sin \phi \quad (7)$$

$$y = \rho \sin \theta \sin \phi \quad (8)$$

$$z = \rho \cos \phi, \quad (9)$$

where  $\theta$  is an azimuthal coordinate running from 0 to  $2\pi$  (LONGITUDE),  $\phi$  is a polar coordinate running from 0 to  $\pi$  (COLATITUDE), and  $\rho$  is the RADIUS. Note that there are several other notations sometimes used in which the symbols for  $\theta$  and  $\phi$  are interchanged or where  $r$  is used instead of  $\rho$ . If  $\rho$  is allowed to run from 0 to a given

RADIUS  $r$ , then a solid BALL is obtained. Converting to "standard" parametric variables  $a = \rho$ ,  $u = \theta$ , and  $v = \phi$  gives the first FUNDAMENTAL FORMS

$$E = a^2 \sin^2 v \quad (10)$$

$$F = 0 \quad (11)$$

$$G = a^2, \quad (12)$$

second FUNDAMENTAL FORMS

$$e = a^2 \sin^2 v \quad (13)$$

$$f = 0 \quad (14)$$

$$g = a^2, \quad (15)$$

AREA ELEMENT

$$dA = a \sin v, \quad (16)$$

GAUSSIAN CURVATURE

$$K = \frac{1}{a^2}, \quad (17)$$

and MEAN CURVATURE

$$H = \frac{1}{a}. \quad (18)$$

A sphere may also be represented parametrically by letting  $u \equiv r \cos \phi$ , so

$$x = \sqrt{r^2 - u^2} \cos \theta \quad (19)$$

$$y = \sqrt{r^2 - u^2} \sin \theta \quad (20)$$

$$z = u, \quad (21)$$

where  $\theta$  runs from 0 to  $2\pi$  and  $u$  runs from  $-r$  to  $r$ .

Given two points on a sphere, the shortest path on the surface of the sphere which connects them (the SPHERE GEODESIC) is an ARC of a CIRCLE known as a GREAT CIRCLE. The equation of the sphere with points  $(x_1, y_1, z_1)$  and  $(x_2, y_2, z_2)$  lying on a DIAMETER is given by

$$(x - x_1)(x - x_2) + (y - y_1)(y - y_2) + (z - z_1)(z - z_2) = 0. \quad (22)$$

Four points are sufficient to uniquely define a sphere. Given the points  $(x_i, y_i, z_i)$  with  $i = 1, 2, 3$ , and 4, the sphere containing them is given by the beautiful DETERMINANT equation

$$\begin{vmatrix} x^2 + y^2 + z^2 & x & y & z & 1 \\ x_1^2 + y_1^2 + z_1^2 & x_1 & y_1 & z_1 & 1 \\ x_2^2 + y_2^2 + z_2^2 & x_2 & y_2 & z_2 & 1 \\ x_3^2 + y_3^2 + z_3^2 & x_3 & y_3 & z_3 & 1 \\ x_4^2 + y_4^2 + z_4^2 & x_4 & y_4 & z_4 & 1 \end{vmatrix} = 0 \quad (23)$$

(Beyer 1987, p. 210).

The generalization of a sphere in  $n$  dimensions is called a **HYPERSPHERE**. An  $n$ -D **HYPERSPHERE** can be specified by the equation

$$x_1^2 + x_2^2 + \dots + x_n^2 = r^2. \quad (24)$$

The distribution of **ANGLES** for random rotation of a sphere is

$$P(\theta) = \frac{2}{\pi} \sin^2(\tfrac{1}{2}\theta), \quad (25)$$

giving a **MEAN** of  $\pi/2 + 2/\pi$ .

To pick a random point on the surface of a sphere, let  $u$  and  $v$  be random variates on  $[0, 1]$ . Then

$$\theta = 2\pi u \quad (26)$$

$$\phi = \cos^{-1}(2v - 1). \quad (27)$$

This works since the **SOLID ANGLE** is

$$d\Omega = \sin \phi \, d\theta \, d\phi = d\theta \, d(\cos \phi). \quad (28)$$

Another easy way to pick a random point on a **SPHERE** is to generate three gaussian random variables  $x$ ,  $y$ , and  $z$ . Then the distribution of the vectors

$$\frac{1}{\sqrt{x^2 + y^2 + z^2}} \begin{bmatrix} x \\ y \\ z \end{bmatrix} \quad (29)$$

is uniform over the surface  $\mathbb{S}^2$ . Another method is to pick  $z$  from a **UNIFORM DISTRIBUTION** over  $[-1, 1]$  and  $\theta$  from a **UNIFORM DISTRIBUTION** over  $[0, 2\pi)$ . Then the points

$$\begin{bmatrix} \sqrt{1-z^2} \cos \theta \\ \sqrt{1-z^2} \sin \theta \\ z \end{bmatrix} \quad (30)$$

are uniformly distributed over  $\mathbb{S}^2$ .

Pick four points on a sphere. What is the probability that the **TETRAHEDRON** having these points as **VERTICES** contains the **CENTER** of the sphere? In the 1-D case, the probability that a second point is on the opposite side of  $1/2$  is  $1/2$ . In the 2-D case, pick two points. In order for the third to form a **TRIANGLE** containing the **CENTER**, it must lie in the quadrant bisected by a **LINE SEGMENT** passing through the center of the **CIRCLE** and the bisector of the two points. This happens for one **QUADRANT**, so the probability is  $1/4$ . Similarly, for a sphere the probability is one **OCTANT**, or  $1/8$ .

Pick two points at random on a unit sphere. The first one can be assigned the coordinate  $(0, 0, 1)$  without loss of generality. The second point can be given the coordinates  $(\sin \phi, 0, \cos \phi)$  with  $\theta \equiv 0$  since all points with the same  $\phi$  are rotationally identical. The distance between the two points is then

$$r = \sqrt{\sin^2 \phi + (1 - \cos \phi)^2} = \sqrt{2 - \cos \phi} = 2 \sin(\tfrac{1}{2}\phi). \quad (31)$$

Because the surface **AREA** element is

$$d\Omega = \sin \phi \, d\theta \, d\phi, \quad (32)$$

the probability that two points are a distance  $r$  apart is

$$\begin{aligned} P_\phi(r) &= \frac{\int_0^\pi \delta(\phi - r) \sin \phi \, d\phi}{\int_0^\pi \sin \phi \, d\phi} \\ &= \tfrac{1}{2} \int_0^\pi \delta[r - 2 \sin(\tfrac{1}{2}\phi)] \sin \phi \, d\phi. \end{aligned} \quad (33)$$

The **DELTA FUNCTION** contributes when

$$\tfrac{1}{2}r = \sin(\tfrac{1}{2}\phi) \quad (34)$$

$$\phi = 2 \sin^{-1}(\tfrac{1}{2}r), \quad (35)$$

so

$$\begin{aligned} P_\phi(r) &= \tfrac{1}{2} \sin[2 \sin^{-1}(\tfrac{1}{2}r)] = \sin[\sin^{-1}(\tfrac{1}{2}r)] \cos[\sin^{-1}(\tfrac{1}{2}r)] \\ &= \tfrac{1}{2}r \sqrt{1 - (\tfrac{1}{2}r)^2} = \tfrac{1}{4}r \sqrt{4 - r^2}. \end{aligned} \quad (36)$$

However, we need

$$P_r(r) \, dr = P_\phi(r) \frac{d\phi}{dr} \, dr, \quad (37)$$

and

$$\begin{aligned} \tfrac{1}{2}dr &= \tfrac{1}{2} \cos(\tfrac{1}{2}\phi) \, d\phi = \tfrac{1}{2} \sqrt{1 - \sin^2(\tfrac{1}{2}\phi)} \, d\phi \\ &= \tfrac{1}{2} \sqrt{1 - (\tfrac{1}{2}r)^2} \, d\phi = \tfrac{1}{4} \sqrt{4 - r^2} \, d\phi \end{aligned} \quad (38)$$

so

$$\frac{d\phi}{dr} = \frac{2}{\sqrt{4 - r^2}}, \quad (39)$$

and

$$P_r(r) = \tfrac{1}{4}r \sqrt{4 - r^2} \frac{2}{\sqrt{4 - r^2}} = \tfrac{1}{2}r \quad (40)$$

for  $r \in [0, 2]$ . Somewhat surprisingly, the largest distances are the most common, contrary to most people's intuition. A plot of 15 random lines is shown below.

The MOMENTS about zero are

$$\mu'_n = \langle r^n \rangle = \int_0^2 r^n dr = \frac{2^{n+1}}{2+n}, \quad (41)$$

giving the first few as

$$\mu'_1 = \frac{4}{3} \quad (42)$$

$$\mu'_2 = 2 \quad (43)$$

$$\mu'_3 = \frac{16}{5} \quad (44)$$

$$\mu'_4 = \frac{16}{3}. \quad (45)$$

Moments about the MEAN are

$$\mu = \frac{4}{3} \quad (46)$$

$$\mu_2 = \sigma^2 = \frac{2}{9} \quad (47)$$

$$\mu_3 = -\frac{8}{135} \quad (48)$$

$$\mu_4 = \frac{16}{135}, \quad (49)$$

so the SKEWNESS and KURTOSIS are

$$\gamma_1 = \frac{4}{5}\sqrt{2} \quad (50)$$

$$\gamma_2 = -\frac{5}{3}. \quad (51)$$

### Sphere-Cylinder Intersection

see CYLINDER-SPHERE INTERSECTION

### Sphere Embedding

A 4-sphere has POSITIVE CURVATURE, with

$$R^2 = x^2 + y^2 + z^2 + w^2 \quad (1)$$

$$2x \frac{dx}{dw} + 2y \frac{dy}{dw} + 2z \frac{dz}{dw} + 2w = 0. \quad (2)$$

Since

$$\mathbf{r} \equiv x\hat{\mathbf{x}} + y\hat{\mathbf{y}} + z\hat{\mathbf{z}}, \quad (3)$$

$$dw = -\frac{x dx + y dy + z dz}{w} = -\frac{\mathbf{r} \cdot d\mathbf{r}}{\sqrt{R^2 - r^2}}. \quad (4)$$

To stay on the surface of the sphere,

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 + dw^2 \\ &= dx^2 + dy^2 + dz^2 + \frac{r^2 dr^2}{R^2 - r^2} \\ &= dr^2 + r^2 d\Omega^2 + \frac{dr^2}{\frac{R^2}{r^2} - 1} \\ &= dr^2 \left( 1 + \frac{1}{\frac{R^2}{r^2} - 1} \right) + r^2 d\Omega^2 \\ &= dr^2 \left( \frac{\frac{R^2}{r^2}}{\frac{R^2}{r^2} - 1} \right) + r^2 d\Omega^2 \\ &= \frac{dr^2}{1 - \frac{r^2}{R^2}} + r^2 d\Omega^2. \end{aligned} \quad (5)$$

With the addition of the so-called expansion parameter, this is the Robertson-Walker line element.

### Sphere Eversion

Smale (1958) proved that it is mathematically possible to turn a SPHERE inside-out without introducing a sharp crease at any point. This means there is a regular homotopy from the standard embedding of the 2-SPHERE in EUCLIDEAN 3-space to the mirror-reflection embedding such that at every stage in the homotopy, the sphere is being IMMERSED in EUCLIDEAN SPACE. This result is so counterintuitive and the proof so technical that the result remained controversial for a number of years.

In 1961, Arnold Shapiro devised an explicit eversion but did not publicize it. Phillips (1966) heard of the result and, in trying to reproduce it, actually devised an independent method of his own. Yet another eversion was devised by Morin, which became the basis for the movie by Max (1977). Morin's eversion also produced explicit algebraic equations describing the process. The original method of Shapiro was subsequently published by Francis and Morin (1979).

## Sphere Geodesic

see GREAT CIRCLE

## Sphere Packing

Let  $\eta$  denote the PACKING DENSITY, which is the fraction of a VOLUME filled by identical packed SPHERES. In 2-D (CIRCLE PACKING), there are two periodic packings for identical CIRCLES: square lattice and hexagonal lattice. Fejes Tóth (1940) proved that the hexagonal lattice is indeed the densest of *all* possible plane packings (Conway and Sloane 1993, pp. 8–9).

In 3-D, there are three periodic packings for identical spheres: cubic lattice, face-centered cubic lattice, and hexagonal lattice. It was hypothesized by Kepler in 1611 that close packing (cubic or hexagonal) is the densest possible (has the greatest  $\eta$ ), and this assertion is known as the KEPLER CONJECTURE. The problem of finding the densest packing of spheres (not necessarily periodic) is therefore known as the KEPLER PROBLEM. The KEPLER CONJECTURE is intuitively obvious, but the proof still remains elusive. However, Gauss (1831) did prove that the face-centered cubic is the densest *lattice* packing in 3-D (Conway and Sloane 1993, p. 9). This result has since been extended to HYPERSPHERE PACKING.

In 3-D, face-centered cubic close packing and hexagonal close packing (which is distinct from hexagonal lattice), both give

$$\eta = \frac{\pi}{3\sqrt{2}} \approx 74.048\%. \quad (1)$$

For packings in 3-D, C. A. Rogers (1958) showed that

$$\eta < \sqrt{18} \left( \cos^{-1} \frac{1}{3} - \frac{1}{3}\pi \right) \approx 77.96355700\% \quad (2)$$

(Le Lionnais 1983). This was subsequently improved to 77.844% (Lindsay 1986), then 77.836% (Muder 1988). However, Rogers (1958) remarks that “many mathematicians believe, and all physicists know” that the actual answer is 74.05% (Conway and Sloane 1993, p. 3).

“Random” close packing in 3-D gives only  $\eta \approx 64\%$  (Jaeger and Nagel 1992).

The PACKING DENSITIES for several packing types are summarized in the following table.

Packing	$\eta$ (exact)	$\eta$ (approx.)
square lattice (2-D)	$\frac{\pi}{4}$	0.7854
hexagonal lattice (2-D)	$\frac{\pi}{2\sqrt{3}}$	0.9069
cubic lattice	$\frac{\pi}{6}$	0.5236
hexagonal lattice	$\frac{\pi}{3\sqrt{3}}$	0.6046
face-centered cubic lattice	$\frac{\pi}{3\sqrt{2}}$	0.7405
random	—	0.6400

For cubic close packing, pack six SPHERES together in the shape of an EQUILATERAL TRIANGLE and place another SPHERE on top to create a TRIANGULAR PYRAMID. Now create another such grouping of seven SPHERES and place the two PYRAMIDS together facing in opposite directions. A CUBE emerges. Consider a face of the CUBE, illustrated below.

The “unit cell” cube contains eight 1/8-spheres (one at each VERTEX) and six HEMISPHERES. The total VOLUME of SPHERES in the unit cell is

$$\begin{aligned} V_{\text{spheres in unit cell}} &= \left( 8 \cdot \frac{1}{8} + 6 \cdot \frac{1}{2} \right) \frac{4\pi}{3} r^3 \\ &= 4 \cdot \frac{4\pi}{3} r^3 = \frac{16}{3} \pi r^3. \end{aligned} \quad (3)$$

The diagonal of the face is  $4r$ , so each side is  $2\sqrt{2}r$ . The VOLUME of the unit cell is therefore

$$V_{\text{unit cell}} = (2\sqrt{2}r)^3 = 16\sqrt{2}r^3. \quad (4)$$

The PACKING DENSITY is therefore

$$\eta_{\text{CCP}} = \frac{\frac{16}{3} \pi r^3}{16\sqrt{2}r^3} = \frac{\pi}{3\sqrt{2}} \quad (5)$$

(Conway and Sloane 1993, p. 2).

Hexagonal close packing must give the same values, since sliding one sheet of SPHERES cannot affect the volume they occupy. To verify this, construct a 3-D diagram containing a hexagonal unit cell with three layers. Both the top and the bottom contain six 1/6-SPHERES and one HEMISPHERE. The total number of spheres in these two rows is therefore

$$2\left(6\frac{1}{6} + 1\frac{1}{2}\right) = 3. \quad (6)$$

The VOLUME of SPHERES in the middle row cannot be simply computed using geometry. However, symmetry requires that the piece of the SPHERE which is cut off is exactly balanced by an extra piece on the other side. There are therefore three SPHERES in the middle layer, for a total of six, and a total VOLUME

$$V_{\text{spheres in unit cell}} = 6 \cdot \frac{4\pi}{3} r^3 (3 + 3) = 8\pi r^3. \quad (7)$$

The base of the HEXAGON is made up of 6 EQUILATERAL TRIANGLES with side lengths  $2r$ . The unit cell base AREA is therefore

$$A_{\text{unit cell}} = 6\left[\frac{1}{2}(2r)(\sqrt{3}r)\right] = 6\sqrt{3}r^2. \quad (8)$$

The height is the same as that of two TETRAHEDRA length  $2r$  on a side, so

$$h_{\text{unit cell}} = 2\left(2r\sqrt{\frac{2}{3}}\right), \quad (9)$$

giving

$$\eta_{\text{HCP}} = \frac{8\pi r^3}{(6\sqrt{3}r^2)\left(4r\sqrt{\frac{2}{3}}\right)} = \frac{\pi}{3\sqrt{2}} \quad (10)$$

(Conway and Sloane 1993, pp. 7 and 9).

If we had actually wanted to compute the VOLUME of SPHERE inside and outside the HEXAGONAL PRISM, we could use the SPHERICAL CAP equation to obtain

$$\begin{aligned} V_C &= \frac{1}{3}\pi h^2(3r - h) = \frac{1}{3}\pi r^3 \frac{1}{3} \left(3 - \frac{1}{\sqrt{3}}\right) \\ &= \frac{1}{9}\pi r^3 \left(3 - \frac{\sqrt{3}}{3}\right) = \frac{1}{27}\pi r^3(9 - \sqrt{3}) \quad (11) \\ V_D &= \pi r^3 \left[\frac{4}{3} - \frac{1}{27}(9 - \sqrt{3})\right] = \frac{1}{27}\pi r^3(36 - 9 + \sqrt{3}) \\ &= \frac{1}{27}\pi r^3(27 + \sqrt{3}). \quad (12) \end{aligned}$$

The rigid packing with *lowest* density known has  $\eta \approx 0.0555$  (Gardner 1966). To be RIGID, each SPHERE must touch at least four others, and the four contact points cannot be in a single HEMISPHERE or all on one equator.

If spheres packed in a cubic lattice, face-centered cubic lattice, and hexagonal lattice are allowed to expand, they form cubes, hexagonal prisms, and rhombic dodecahedra. Compressing a random packing gives polyhedra with an average of 13.3 faces (Coxeter 1958, 1961).

For sphere packing inside a CUBE, see Goldberg (1971) and Schaer (1966).

## Sphere Point Picking

see FEJES TÓTH'S PROBLEM

## Sphere-Sphere Intersection

Let two spheres of RADII  $R$  and  $r$  be located along the  $x$ -AXIS centered at  $(0, 0, 0)$  and  $(d, 0, 0)$ , respectively. Not surprisingly, the analysis is very similar to the case of

the CIRCLE-CIRCLE INTERSECTION. The equations of the two SPHERES are

$$x^2 + y^2 + z^2 = R^2 \quad (1)$$

$$(x - d)^2 + y^2 + z^2 = r^2. \quad (2)$$

Combining (1) and (2) gives

$$(x - d)^2 + (R^2 - x^2) = r^2. \quad (3)$$

Multiplying through and rearranging give

$$x^2 - 2dx + d^2 - x^2 = r^2 - R^2. \quad (4)$$

Solving for  $x$  gives

$$x = \frac{d^2 - r^2 + R^2}{2d}. \quad (5)$$

The intersection of the SPHERES is therefore a curve lying in a PLANE parallel to the  $yz$ -plane at a single  $x$ -coordinate. Plugging this back into (1) gives

$$\begin{aligned} y^2 + z^2 &= R^2 - x^2 = R^2 - \left( \frac{d^2 - r^2 + R^2}{2d} \right)^2 \\ &= \frac{4d^2 R^2 - (d^2 - r^2 + R^2)^2}{4d^2}, \end{aligned} \quad (6)$$

which is a CIRCLE with RADIUS

$$\begin{aligned} a &= \frac{1}{2d} \sqrt{4d^2 R^2 - (d^2 - r^2 + R^2)^2} \\ &= \frac{1}{2d} [(-d + r - R)(-d - r + R) \\ &\quad \times [(-d + r + R)(d + r + R)]^{1/2}. \end{aligned} \quad (7)$$

The VOLUME of the 3-D LENS common to the two spheres can be found by adding the two SPHERICAL CAPS. The distances from the SPHERES' centers to the bases of the caps are

$$d_1 = x \quad (8)$$

$$d_2 = d - x, \quad (9)$$

so the heights of the caps are

$$h_1 = R - d_1 = \frac{(r - R + d)(r + R - d)}{2d} \quad (10)$$

$$h_2 = r - d_2 = \frac{(R - r + d)(R + r - d)}{2d}. \quad (11)$$

The VOLUME of a SPHERICAL CAP of height  $h'$  for a SPHERE of RADIUS  $R'$  is

$$V(R', h') = \frac{1}{3} \pi h'^2 (3R' - h'). \quad (12)$$

Letting  $R_1 = R$  and  $R_2 = r$  and summing the two caps gives

$$\begin{aligned} V &= V(R_1, h_1) + V(R_2, h_2) \\ &= \frac{\pi(R + r - d)^2 (d^2 + 2dr - 3r^2 + 2dR + 6rR - 3R^2)}{12d}. \end{aligned} \quad (13)$$

This expression gives  $V = 0$  for  $d = r + R$  as it must. In the special case  $r = R$ , the VOLUME simplifies to

$$V = \frac{1}{12} \pi (4R + d)(2R - d)^2. \quad (14)$$

see also APPLE, CIRCLE-CIRCLE INTERSECTION, DOUBLE BUBBLE, LENS, SPHERE

### Sphere with Tunnel

Find the tunnel between two points  $A$  and  $B$  on a gravitating SPHERE which gives the shortest transit time under the force of gravity. Assume the SPHERE to be nonrotating, of RADIUS  $a$ , and with uniform density  $\rho$ . Then the standard form EULER-LAGRANGE DIFFERENTIAL EQUATION in polar coordinates is

$$r_{\phi\phi}(r^3 - ra^2) + r_{\phi}^2(2a^2 - r^2) + a^2 r^2 = 0, \quad (1)$$

along with the boundary conditions  $r(\phi = 0) = r_0$ ,  $r_{\phi}(\phi = 0) = 0$ ,  $r(\phi = \phi_A) = a$ , and  $r(\phi = \phi_B) = a$ . Integrating once gives

$$r_{\phi}^2 = \frac{a^2 r^2}{r_0^2} \frac{r^2 - r_0^2}{a^2 - r^2}. \quad (2)$$

But this is the equation of a HYPOCYCLOID generated by a CIRCLE of RADIUS  $\frac{1}{2}(a - r_0)$  rolling inside the CIRCLE of RADIUS  $a$ , so the tunnel is shaped like an arc of a HYPOCYCLOID. The transit time from point  $A$  to point  $B$  is

$$T = \pi \sqrt{\frac{a^2 - r_0^2}{ag}}, \quad (3)$$

where

$$g = \frac{GM}{a^2} = \frac{4}{3} \pi \rho G a \quad (4)$$

is the surface gravity with  $G$  the universal gravitational constant.

### Spherical Bessel Differential Equation

Take the HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2 F + k^2 F = 0 \quad (1)$$

in SPHERICAL COORDINATES. This is just LAPLACE'S EQUATION in SPHERICAL COORDINATES with an additional term,

$$\begin{aligned} \frac{d^2 R}{dr^2} \Phi \Theta + \frac{2}{r} \frac{dR}{dr} + \frac{1}{r^2 \sin^2 \phi} \frac{d^2 \Theta}{d\theta^2} \Phi R \\ + \frac{\cos \phi}{r^2 \sin \phi} \frac{d\Phi}{d\phi} \Theta R + \frac{1}{r^2} \frac{d^2 \Phi}{d\phi^2} + k^2 R \Phi \Theta = 0. \end{aligned} \quad (2)$$

Multiply through by  $r^2/R\Phi\Theta$ ,

$$\frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{2r}{R} \frac{dR}{dr} + k^2 r^2 + \frac{1}{\Theta \sin^2 \phi} \frac{d^2 \Theta}{d\theta^2} + \frac{\cos \phi}{\Phi \sin \phi} \frac{d\Phi}{d\phi} + \frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2} = 0. \quad (3)$$

This equation is separable in  $R$ . Call the separation constant  $n(n+1)$ ,

$$\frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{2r}{R} \frac{dR}{dr} + k^2 r^2 = n(n+1). \quad (4)$$

Now multiply through by  $R$ ,

$$r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} + [k^2 r^2 - n(n+1)]R = 0. \quad (5)$$

This is the SPHERICAL BESSEL DIFFERENTIAL EQUATION. It can be transformed by letting  $x \equiv kr$ , then

$$r \frac{dR(r)}{dr} = kr \frac{dR(r)}{k dr} = kr \frac{dR(r)}{d(kr)} = x \frac{dR(r)}{dx}. \quad (6)$$

Similarly,

$$r^2 \frac{d^2 R(r)}{dr^2} = x^2 \frac{d^2 R(r)}{dx^2}, \quad (7)$$

so the equation becomes

$$x^2 \frac{d^2 R}{dx^2} + 2x \frac{dR}{dx} + [x^2 - n(n+1)]R = 0. \quad (8)$$

Now look for a solution of the form  $R(r) = Z(x)x^{-1/2}$ , denoting a derivative with respect to  $x$  by a prime,

$$R' = Z'x^{-1/2} - \frac{1}{2}Zx^{-3/2} \quad (9)$$

$$\begin{aligned} R'' &= Z''x^{-1/2} - \frac{1}{2}Z'x^{-3/2} - \frac{1}{2}Z'x^{-3/2} \\ &\quad - \frac{1}{2}\left(-\frac{3}{2}\right)Zx^{-5/2} \\ &= Z''x^{-1/2} - Z'x^{-3/2} + \frac{3}{4}Zx^{-5/2}, \end{aligned} \quad (10)$$

so

$$\begin{aligned} x^2(Z''x^{-1/2} - Z'x^{-3/2} + \frac{3}{4}Zx^{-5/2}) \\ + 2x(Z'x^{-1/2} - \frac{1}{2}Zx^{-3/2}) + [x^2 - n(n+1)]Zx^{-1/2} = 0 \end{aligned} \quad (11)$$

$$\begin{aligned} x^2(Z'' - Z'x^{-1} + \frac{3}{4}Zx^{-2}) + 2x(Z' - \frac{1}{2}Zx^{-1}) \\ + [x^2 - n(n+1)]Z = 0 \end{aligned} \quad (12)$$

$$x^2 Z'' + (-x+2x)Z' + [\frac{3}{4} - 1 + x^2 - n(n+1)]Z = 0 \quad (13)$$

$$\begin{aligned} x^2 Z'' + xZ' + [x^2 - (n^2 + n + \frac{1}{4})]Z &= 0 \\ x^2 Z'' + xZ' + [x^2 - (n + \frac{1}{2})^2]Z &= 0. \end{aligned} \quad (14)$$

But the solutions to this equation are BESSEL FUNCTIONS of half integral order, so the normalized solutions to the original equation are

$$R(r) \equiv A \frac{J_{n+1/2}(kr)}{\sqrt{kr}} + B \frac{Y_{n+1/2}(kr)}{\sqrt{kr}} \quad (15)$$

which are known as SPHERICAL BESSEL FUNCTIONS. The two types of solutions are denoted  $j_n(x)$  (SPHERICAL BESSEL FUNCTION OF THE FIRST KIND) or  $n_n(x)$  (SPHERICAL BESSEL FUNCTION OF THE SECOND KIND), and the general solution is written

$$R(r) = A' j_n(kr) + B' n_n(kr), \quad (16)$$

where

$$j_n(z) \equiv \sqrt{\frac{\pi}{2}} \frac{J_{n+1/2}(z)}{\sqrt{z}} \quad (17)$$

$$n_n(z) \equiv \sqrt{\frac{\pi}{2}} \frac{Y_{n+1/2}(z)}{\sqrt{z}}. \quad (18)$$

## Spherical Bessel Function of the First Kind

$$\begin{aligned}
 j_n(x) &\equiv \sqrt{\frac{\pi}{2x}} J_{n+1/2}(x) \\
 &= 2^n x^n \sum_{s=0}^{\infty} \frac{(-1)^s (s-n)!}{s! (2s+2n+1)!} x^{2s} \\
 &= \frac{x^n}{(2n+1)!!} \left[ 1 - \frac{\frac{1}{2}x^2}{1!(2n+3)} \right. \\
 &\quad \left. + \frac{\left(\frac{1}{2}x^2\right)^2}{2!(2n+3)(2n+5)} + \dots \right] \\
 &= (-1)^n x^n \left( \frac{d}{x dx} \right)^n \frac{\sin x}{x}.
 \end{aligned}$$

The first few functions are

$$\begin{aligned}
 j_0(x) &= \frac{\sin x}{x} \\
 j_1(x) &= \frac{\sin x}{x^2} - \frac{\cos x}{x} \\
 j_2(x) &= \left( \frac{3}{x^3} - \frac{1}{x} \right) \sin x - \frac{3}{x^2} \cos x.
 \end{aligned}$$

## Spherical Bessel Function of the Second Kind

$$\begin{aligned}
 n_n(x) &\equiv \sqrt{\frac{\pi}{2x}} Y_{n+1/2}(x) \\
 &= \frac{(-1)^{n+1}}{2^n x^{n+1}} \sum_{s=0}^{\infty} \frac{(-1)^s (s-n)!}{s! (2s-2n)!} x^{2s} \\
 &= -\frac{(2n-1)!!}{x^{n+1}} \left[ 1 - \frac{\frac{1}{2}x^2}{1!(1-2n)} \right. \\
 &\quad \left. + \frac{\left(\frac{1}{2}x^2\right)^2}{2!(1-2n)(3-2n)} + \dots \right] \\
 &= (-1)^{n+1} \sqrt{\frac{\pi}{2x}} J_{-n-1/2}(x).
 \end{aligned}$$

The first few functions are

$$\begin{aligned}
 n_0(x) &= -\frac{\cos x}{x} \\
 n_1(x) &= -\frac{\cos x}{x^2} - \frac{\sin x}{x} \\
 n_2(x) &= -\left( \frac{3}{x^3} - \frac{1}{x} \right) \cos x - \frac{3}{x^2} \sin x.
 \end{aligned}$$

## Spherical Bessel Function of the Third Kind

see SPHERICAL HANKEL FUNCTION OF THE FIRST KIND, SPHERICAL HANKEL FUNCTION OF THE SECOND KIND

## Spherical Cap

A spherical cap is the region of a SPHERE which lies above (or below) a given PLANE. If the PLANE passes through the CENTER of the SPHERE, the cap is a HEMI-SPHERE. Let the SPHERE have RADIUS  $R$ , then the VOLUME of a spherical cap of height  $h$  and base RADIUS  $a$  is

given by the equation of a SPHERICAL SEGMENT (which is a spherical cut by a second PLANE)

$$V_{\text{spherical segment}} = \frac{1}{6}\pi h(3a^2 + 3b^2 + h^2) \quad (1)$$

with  $b = 0$ , giving

$$V_{\text{cap}} = \frac{1}{6}\pi h(3a^2 + h^2). \quad (2)$$

Using the PYTHAGOREAN THEOREM gives

$$(R - h)^2 + a^2 = R^2, \quad (3)$$

which can be solved for  $a^2$  as

$$a^2 = 2Rh - h^2, \quad (4)$$

and plugging this in gives the equivalent formula

$$V_{\text{cap}} = \frac{1}{3}\pi h^2(3R - h). \quad (5)$$

In terms of the so-called CONTACT ANGLE (the angle between the normal to the sphere at the bottom of the cap and the base plane)

$$R - h = R \sin \theta \quad (6)$$

$$\alpha \equiv \sin^{-1} \left( \frac{R - h}{R} \right), \quad (7)$$

so

$$V_{\text{cap}} = \frac{1}{3}\pi R^3(2 - 3 \sin \alpha + \sin^3 \alpha). \quad (8)$$

Consider a cylindrical box enclosing the cap so that the top of the box is tangent to the top of the SPHERE. Then the enclosing box has VOLUME

$$\begin{aligned} V_{\text{box}} &= \pi a^2 h = \pi(R \cos \alpha)[R(1 - \sin \alpha)] \\ &= \pi R^3(1 - \sin \alpha - \sin^2 \alpha + \sin^3 \alpha), \end{aligned} \quad (9)$$

so the hollow volume between the cap and box is given by

$$V_{\text{box}} - V_{\text{cap}} = \frac{1}{3}\pi R^3(1 - 3 \sin^2 \alpha + 2 \sin^3 \alpha). \quad (10)$$

If a second PLANE cuts the cap, the resulting SPHERICAL FRUSTUM is called a SPHERICAL SEGMENT. The SURFACE AREA of the spherical cap is given by the same equation as for a general ZONE:

$$S_{\text{cap}} = 2\pi R h. \quad (11)$$

see also CONTACT ANGLE, DOME, FRUSTUM, HEMI-SPHERE, SOLID OF REVOLUTION, SPHERE, SPHERICAL SEGMENT, TORISPHERICAL DOME, ZONE

## Spherical Coordinates

A system of CURVILINEAR COORDINATES which is natural for describing positions on a SPHERE or SPHEROID. Define  $\theta$  to be the azimuthal ANGLE in the  $xy$ -PLANE from the  $x$ -AXIS with  $0 \leq \theta < 2\pi$  (denoted  $\lambda$  when referred to as the LONGITUDE),  $\phi$  to be the polar ANGLE from the  $z$ -AXIS with  $0 \leq \phi \leq \pi$  (COLATITUDE, equal to  $\phi = 90^\circ - \delta$  where  $\delta$  is the LATITUDE), and  $r$  to be distance (RADIUS) from a point to the ORIGIN.

Unfortunately, the convention in which the symbols  $\theta$  and  $\phi$  are reversed is frequently used, especially in physics, leading to unnecessary confusion. The symbol  $\rho$  is sometimes also used in place of  $r$ . Arfken (1985) uses  $(r, \phi, \theta)$ , whereas Beyer (1987) uses  $(\rho, \theta, \phi)$ . Be very careful when consulting the literature.

In this work, the symbols for the azimuthal, polar, and radial coordinates are taken as  $\theta$ ,  $\phi$ , and  $r$ , respectively. Note that this definition provides a logical extension of the usual POLAR COORDINATES notation, with  $\theta$  remaining the ANGLE in the  $xy$ -PLANE and  $\phi$  becoming the ANGLE out of the PLANE.

$$r = \sqrt{x^2 + y^2 + z^2} \quad (1)$$

$$\theta = \tan^{-1} \left( \frac{y}{x} \right) \quad (2)$$

$$\phi = \sin^{-1} \left( \frac{\sqrt{x^2 + y^2}}{r} \right) = \cos^{-1} \left( \frac{z}{r} \right), \quad (3)$$

where  $r \in [0, \infty)$ ,  $\theta \in [0, 2\pi)$ , and  $\phi \in [0, \pi]$ . In terms of CARTESIAN COORDINATES,

$$x = r \cos \theta \sin \phi \quad (4)$$

$$y = r \sin \theta \sin \phi \quad (5)$$

$$z = r \cos \phi. \quad (6)$$

The SCALE FACTORS are

$$h_r = 1 \quad (7)$$

$$h_\theta = r \sin \phi \quad (8)$$

$$h_\phi = r, \quad (9)$$

so the METRIC COEFFICIENTS are

$$g_{rr} = 1 \quad (10)$$

$$g_{\theta\theta} = r^2 \sin^2 \phi \quad (11)$$

$$g_{\phi\phi} = r^2. \quad (12)$$

The LINE ELEMENT is

$$ds = dr \hat{\mathbf{r}} + r d\phi \hat{\boldsymbol{\phi}} + r \sin \phi d\theta \hat{\boldsymbol{\theta}}, \quad (13)$$

the AREA element

$$d\mathbf{a} = r^2 \sin \phi d\theta d\phi \hat{\mathbf{r}}, \quad (14)$$

and the VOLUME ELEMENT

$$dV = r^2 \sin \phi d\theta d\phi dr. \quad (15)$$

The JACOBIAN is

$$\left| \frac{\partial(x, y, z)}{\partial(r, \theta, \phi)} \right| = r^2 |\sin \phi|. \quad (16)$$

The POSITION VECTOR is

$$\mathbf{r} \equiv \begin{bmatrix} r \cos \theta \sin \phi \\ r \sin \theta \sin \phi \\ r \cos \phi \end{bmatrix}, \quad (17)$$

so the UNIT VECTORS are

$$\hat{\mathbf{r}} \equiv \frac{d\mathbf{r}}{\left| \frac{d\mathbf{r}}{dr} \right|} = \begin{bmatrix} \cos \theta \sin \phi \\ \sin \theta \sin \phi \\ \cos \phi \end{bmatrix} \quad (18)$$

$$\hat{\boldsymbol{\theta}} \equiv \frac{d\mathbf{r}}{\left| \frac{d\mathbf{r}}{d\theta} \right|} = \begin{bmatrix} -\sin \theta \\ \cos \theta \\ 0 \end{bmatrix} \quad (19)$$

$$\hat{\boldsymbol{\phi}} \equiv \frac{d\mathbf{r}}{\left| \frac{d\mathbf{r}}{d\phi} \right|} = \begin{bmatrix} \cos \theta \cos \phi \\ \sin \theta \cos \phi \\ -\sin \phi \end{bmatrix}. \quad (20)$$

Derivatives of the UNIT VECTORS are

$$\frac{\partial \hat{\mathbf{r}}}{\partial r} = \mathbf{0} \quad (21)$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial r} = \mathbf{0} \quad (22)$$

$$\frac{\partial \hat{\boldsymbol{\phi}}}{\partial r} = \mathbf{0} \quad (23)$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial \theta} = \begin{bmatrix} -\sin \theta \sin \phi \\ \cos \theta \sin \phi \\ 0 \end{bmatrix} = \sin \phi \hat{\boldsymbol{\theta}} \quad (24)$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial \theta} = \begin{bmatrix} -\cos \theta \\ -\sin \theta \\ 0 \end{bmatrix} = -\cos \phi \hat{\boldsymbol{\phi}} - \sin \phi \hat{\mathbf{r}} \quad (25)$$

$$\frac{\partial \hat{\boldsymbol{\phi}}}{\partial \theta} = \begin{bmatrix} -\sin \theta \cos \phi \\ \cos \theta \cos \phi \\ 0 \end{bmatrix} = \cos \phi \hat{\boldsymbol{\theta}} \quad (26)$$

$$\frac{\partial \hat{\mathbf{r}}}{\partial \phi} = \begin{bmatrix} \cos \theta \\ \sin \theta \cos \phi \\ -\sin \phi \end{bmatrix} = \hat{\boldsymbol{\phi}} \quad (27)$$

$$\frac{\partial \hat{\boldsymbol{\theta}}}{\partial \phi} = \mathbf{0} \quad (28)$$

$$\frac{\partial \hat{\boldsymbol{\phi}}}{\partial \phi} = \begin{bmatrix} -\cos \theta \sin \phi \\ -\sin \theta \sin \phi \\ -\cos \phi \end{bmatrix} = -\hat{\mathbf{r}}. \quad (29)$$

The GRADIENT is

$$\nabla = \hat{\mathbf{r}} \frac{\partial}{\partial r} + \frac{1}{r} \hat{\boldsymbol{\phi}} \frac{\partial}{\partial \phi} + \frac{1}{r \sin \phi} \hat{\boldsymbol{\theta}} \frac{\partial}{\partial \theta}, \quad (30)$$

so

$$\nabla_r \hat{\mathbf{r}} = \mathbf{0} \quad (31)$$

$$\nabla_r \hat{\boldsymbol{\theta}} = \mathbf{0} \quad (32)$$

$$\nabla_r \hat{\boldsymbol{\phi}} = \hat{\boldsymbol{\theta}} \quad (33)$$

$$\nabla_\theta \hat{\mathbf{r}} = \frac{\sin \phi \hat{\boldsymbol{\theta}}}{r \sin \phi} = \frac{1}{r} \hat{\boldsymbol{\theta}} \quad (34)$$

$$\nabla_\theta \hat{\boldsymbol{\theta}} = -\frac{\cos \phi \hat{\boldsymbol{\phi}} + \sin \phi \hat{\mathbf{r}}}{r \sin \phi} = -\frac{\cot \phi}{r} \hat{\boldsymbol{\phi}} - \frac{1}{r} \hat{\mathbf{r}} \quad (35)$$

$$\nabla_\theta \hat{\boldsymbol{\phi}} = \frac{\cos \phi \hat{\boldsymbol{\phi}}}{r \sin \phi} = \frac{1}{r} \cot \phi \hat{\boldsymbol{\theta}}. \quad (36)$$

Now, since the CONNECTION COEFFICIENTS are given by  $\Gamma_{jk}^i = \hat{\mathbf{x}}_i \cdot (\nabla_k \hat{\mathbf{x}}_j)$ ,

$$\Gamma^\theta = \begin{bmatrix} 0 & \frac{1}{r} & 0 \\ 0 & 0 & 0 \\ 0 & \frac{\cot \phi}{r} & 0 \end{bmatrix} \quad (37)$$

$$\Gamma^\phi = \begin{bmatrix} 0 & 0 & \frac{1}{r} \\ 0 & -\frac{\cot \phi}{r} & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (38)$$

$$\Gamma^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -\frac{1}{r} & 0 \\ 0 & 0 & -\frac{1}{r} \end{bmatrix}. \quad (39)$$

The DIVERGENCE is

$$\begin{aligned} \nabla \cdot \mathbf{F} &= A_{,k}^k + \Gamma_{jk}^k A^j \\ &= [A_{,r}^r + (\Gamma_{rr}^r A^r + \Gamma_{\theta r}^r A^\theta + \Gamma_{\phi r}^r A^\phi) \\ &\quad + [A_{,\theta}^\theta + (\Gamma_{r\theta}^\theta A^r + \Gamma_{\theta\theta}^\theta A^\theta + \Gamma_{\phi\theta}^\theta A^\phi)] \\ &\quad + [A_{,\phi}^\phi + (\Gamma_{r\phi}^\phi A^r + \Gamma_{\theta\phi}^\phi A^\theta + \Gamma_{\phi\phi}^\phi A^\phi)]] \\ &= \frac{1}{g_r} \frac{\partial A^r}{\partial r} + \frac{1}{g_\theta} \frac{\partial A^\theta}{\partial \theta} + \frac{1}{g_\phi} \frac{\partial A^\phi}{\partial \phi} + (0 + 0 + 0) \\ &\quad + \left( \frac{1}{r} A^r + 0 + \frac{\cot \phi}{r} A^\phi \right) + \left( \frac{1}{r} A^r + 0 + 0 \right) \\ &= \frac{\partial}{\partial r} A^r + \frac{2}{r} A^r + \frac{1}{r \sin \phi} \frac{\partial}{\partial \theta} A^\theta + \frac{1}{r} \frac{\partial}{\partial \phi} A^\phi + \frac{\cot \phi}{r} A^\phi, \end{aligned} \quad (40)$$

or, in VECTOR notation,

$$\begin{aligned} \nabla \cdot \mathbf{F} &= \left( \frac{2}{r} + \frac{\partial}{\partial r} \right) F_r + \left( \frac{1}{r} \frac{\partial}{\partial \phi} + \frac{\cot \phi}{r} \right) F_\phi + \frac{1}{\sin \phi} \frac{\partial F_\theta}{\partial \theta} \\ &= \frac{1}{r^2} \frac{\partial}{\partial r} (r^2 F_r) + \frac{1}{r \sin \phi} \frac{\partial}{\partial \phi} (\sin \phi F_\phi) + \frac{1}{r \sin \phi} \frac{\partial F_\theta}{\partial \theta}. \end{aligned} \quad (41)$$

The COVARIANT DERIVATIVES are given by

$$A_{j;k} = \frac{1}{g_{kk}} \frac{\partial A_j}{\partial x_k} - \Gamma_{jk}^i A_i, \quad (42)$$

so

$$A_{r;r} = \frac{\partial A_r}{\partial r} - \Gamma_{rr}^i A_i = \frac{\partial A_r}{\partial r} \quad (43)$$

$$\begin{aligned} A_{r;\theta} &= \frac{1}{r \sin \phi} \frac{\partial A_r}{\partial \theta} - \Gamma_{r\theta}^i = \frac{1}{r \sin \phi} \frac{\partial A_r}{\partial \theta} - \Gamma_{r\theta} A_\theta \\ &= \frac{1}{r \sin \phi} \frac{\partial A_r}{\partial \phi} - \frac{A_\theta}{r} \end{aligned} \quad (44)$$

$$\begin{aligned} A_{r;\phi} &= \frac{1}{r} \frac{\partial A_r}{\partial \phi} - \Gamma_{r\phi}^i A_i = \frac{1}{r} \frac{\partial A_r}{\partial \phi} - \Gamma_{r\phi}^\phi A_\phi \\ &= \frac{1}{r} \left( \frac{\partial A_r}{\partial \phi} - A_\phi \right) \end{aligned} \quad (45)$$

$$A_{\theta;r} = \frac{\partial A_\theta}{\partial r} - \Gamma_{\theta r}^i A_i = \frac{\partial A_\theta}{\partial r} \quad (46)$$

$$\begin{aligned} A_{\theta;\theta} &= \frac{1}{r \sin \phi} \frac{\partial A_\theta}{\partial \theta} - \Gamma_{\theta\theta}^i A_i \\ &= \frac{1}{r \sin \phi} \frac{\partial A_\theta}{\partial \theta} - \Gamma_{\theta\theta}^\phi A_\phi - \Gamma_{\theta\theta}^r A_r \\ &= \frac{1}{r \sin \phi} \frac{\partial A_\theta}{\partial \theta} + \frac{\cot \phi}{r} A_\phi + \frac{A_r}{r} \end{aligned} \quad (47)$$

$$A_{\theta;\phi} = \frac{1}{r} \frac{\partial A_\theta}{\partial r} - \Gamma_{\theta\phi}^i A_i \frac{\partial A_\theta}{\partial \phi} \quad (48)$$

$$A_{\phi;r} = \frac{\partial A_\phi}{\partial r} - \Gamma_{\phi r}^i A_i = \frac{\partial A_\phi}{\partial r} \quad (49)$$

$$\begin{aligned} A_{\phi;\theta} &= \frac{1}{r \sin \phi} \frac{\partial A_\phi}{\partial \theta} - \Gamma_{\phi\theta}^i A_i = \frac{1}{r \sin \phi} \frac{\partial A_\phi}{\partial \theta} - \Gamma_{\phi\theta}^\theta A_\theta \\ &= \frac{1}{r \sin \phi} \frac{\partial A_\phi}{\partial \theta} - \frac{\cot \phi}{r} A_\theta \end{aligned} \quad (50)$$

$$\begin{aligned} A_{\phi;\phi} &= \frac{1}{r} \frac{\partial A_\phi}{\partial \phi} - \Gamma_{\phi\phi}^i A_i = \frac{1}{r} \frac{\partial A_\phi}{\partial \phi} - \Gamma_{\phi\phi}^r A_r \\ &= \frac{1}{r} \frac{\partial A_\phi}{\partial \phi} + \frac{A_r}{r}. \end{aligned} \quad (51)$$

The COMMUTATION COEFFICIENTS are given by

$$c_{\alpha\beta}^\mu \vec{e}_\mu = [\vec{e}_\alpha, \vec{e}_\beta] = \nabla_\alpha \vec{e}_\beta - \nabla_\beta \vec{e}_\alpha \quad (52)$$

$$[\hat{r}, \hat{r}] = [\hat{\theta}, \hat{\theta}] = [\hat{\phi}, \hat{\phi}] = \mathbf{0}, \quad (53)$$

so  $c_{rr}^\alpha = c_{\theta\theta}^\alpha = c_{\phi\phi}^\alpha = 0$ , where  $\alpha = r, \theta, \phi$ .

$$[\hat{r}, \hat{\theta}] = -[\hat{\theta}, \hat{r}] = \nabla_r \hat{\theta} - \nabla_\theta \hat{r} = \mathbf{0} - \frac{1}{r} \hat{\theta} = -\frac{1}{r} \hat{\theta}, \quad (54)$$

so  $c_{r\theta}^\theta = -c_{\theta r}^\theta = -\frac{1}{r}$ ,  $c_{r\theta}^r = c_{\theta r}^r = 0$ .

$$[\hat{r}, \hat{\phi}] = -[\hat{\phi}, \hat{r}] = \mathbf{0} - \frac{1}{r} \hat{\phi} = -\frac{1}{r} \hat{\phi}, \quad (55)$$

so  $c_{r\phi}^\phi = -c_{\phi r}^\phi = \frac{1}{r}$ .

$$[\hat{\theta}, \hat{\phi}] = -[\hat{\phi}, \hat{\theta}] = \frac{1}{r} \cot \phi \hat{\theta} - \mathbf{0} = \frac{1}{r} \cot \phi \hat{\theta}, \quad (56)$$

so

$$c_{\theta\phi}^\theta = -c_{\phi\theta}^\theta = \frac{1}{r} \cot \phi. \quad (57)$$

Summarizing,

$$c^r = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \quad (58)$$

$$c^\theta = \begin{bmatrix} 0 & -\frac{1}{r} & 0 \\ \frac{1}{r} & 0 & \frac{1}{r} \cot \phi \\ 0 & -\frac{1}{r} \cot \phi & 0 \end{bmatrix} \quad (59)$$

$$c^\phi = \begin{bmatrix} 0 & 0 & -\frac{1}{r} \\ 0 & 0 & 0 \\ \frac{1}{r} & 0 & 0 \end{bmatrix}. \quad (60)$$

Time derivatives of the POSITION VECTOR are

$$\begin{aligned} \dot{\mathbf{r}} &= \begin{bmatrix} \cos \theta \sin \phi \dot{r} - r \sin \theta \sin \phi \dot{\theta} + r \cos \theta \cos \phi \dot{\phi} \\ \sin \theta \sin \phi \dot{r} + r \cos \theta \sin \phi \dot{\theta} + r \sin \theta \cos \phi \dot{\phi} \\ \cos \phi \dot{r} - r \sin \phi \dot{\phi} \end{bmatrix} \\ &= \begin{bmatrix} \cos \theta \sin \phi \\ \sin \theta \sin \phi \\ \cos \phi \end{bmatrix} \dot{r} + r \sin \phi \begin{bmatrix} -\sin \theta \\ \cos \theta \\ 0 \end{bmatrix} \dot{\theta} \\ &\quad + r \begin{bmatrix} \cos \theta \cos \phi \\ \sin \theta \cos \phi \\ -\sin \phi \end{bmatrix} \dot{\phi} \\ &= \dot{r} \hat{r} + r \sin \phi \dot{\theta} \hat{\theta} + r \dot{\phi} \hat{\phi}. \end{aligned} \quad (61)$$

The SPEED is therefore given by

$$v \equiv |\dot{\mathbf{r}}| = \sqrt{\dot{r}^2 + r^2 \sin^2 \phi \dot{\theta}^2 + r^2 \dot{\phi}^2}. \quad (62)$$

The ACCELERATION is

$$\begin{aligned} \ddot{\mathbf{r}} &= (-\sin \theta \sin \phi \ddot{r} + \cos \theta \cos \phi \dot{r} \dot{\phi} + \cos \theta \sin \phi \ddot{\theta}) \\ &\quad - (\sin \theta \sin \phi \ddot{r} + r \cos \theta \sin \phi \dot{\theta}^2 + r \sin \theta \cos \phi \dot{\phi} \dot{\theta} \\ &\quad + r \sin \theta \sin \phi \ddot{\theta}) + (\cos \theta \cos \phi \ddot{r} - r \sin \theta \cos \phi \dot{\theta} \dot{\phi} \\ &\quad - r \cos \theta \sin \phi \dot{\phi}^2 + r \cos \theta \cos \phi \ddot{\phi}) \\ &= -2 \sin \theta \sin \phi \dot{\theta} \dot{r} + 2 \cos \theta \cos \phi \dot{r} \dot{\phi} - 2r \sin \theta \cos \phi \dot{\theta} \dot{\phi} \\ &\quad + \cos \theta \sin \phi \ddot{r} - r \sin \theta \sin \phi \ddot{\theta} + r \cos \theta \cos \phi \ddot{\phi} \\ &\quad - r \cos \theta \sin \phi (\dot{\theta}^2 + \dot{\phi}^2) \end{aligned} \quad (63)$$

$$\begin{aligned} \ddot{\mathbf{y}} &= (\sin \theta \sin \phi \ddot{r} + r \cos \theta \sin \phi \dot{\theta} \dot{\phi} + r \cos \phi \sin \theta \dot{\phi} \dot{\theta}) \\ &\quad + (\cos \theta \sin \phi \ddot{r} - r \sin \theta \sin \phi \dot{\theta}^2 + r \cos \theta \cos \phi \dot{\phi} \dot{\theta} \\ &\quad + r \cos \theta \sin \phi \ddot{\theta}) + (\sin \theta \cos \phi \ddot{r} + r \cos \theta \cos \phi \dot{\theta} \dot{\phi} \\ &\quad - r \sin \theta \sin \phi \dot{\phi}^2 + r \sin \theta \cos \phi \ddot{\phi}) \\ &= 2 \cos \theta \sin \phi \dot{\theta} \dot{r} + 2 \sin \theta \cos \phi \dot{r} \dot{\phi} + 2r \cos \theta \cos \phi \dot{\theta} \dot{\phi} \\ &\quad + \sin \theta \sin \phi \ddot{r} + r \cos \theta \sin \phi \ddot{\theta} + r \sin \theta \cos \phi \ddot{\phi} \\ &\quad - r \sin \theta \sin \phi (\dot{\theta}^2 + \dot{\phi}^2) \end{aligned} \quad (64)$$

$$\begin{aligned} \ddot{\mathbf{z}} &= (\cos \phi \ddot{r} - \sin \phi \dot{r} \dot{\phi}) - (\dot{r} \sin \phi \dot{\phi} + r \cos \phi \dot{\phi}^2 + r \sin \phi \ddot{\phi}) \\ &= -r \cos \phi \dot{\phi}^2 + \cos \phi \ddot{r} - 2 \sin \phi \dot{r} \dot{\phi} - r \sin \phi \ddot{\phi}. \end{aligned} \quad (65)$$

Plugging these in gives

$$\begin{aligned}\ddot{\mathbf{r}} = & (\ddot{r} - r\dot{\phi}^2) \begin{bmatrix} \cos \theta \sin \phi \\ \sin \theta \sin \phi \\ \cos \phi \end{bmatrix} \\ & + (2r \cos \phi \dot{\theta} \dot{\phi} + r \sin \phi \ddot{\theta}) \begin{bmatrix} -\sin \theta \\ \cos \theta \\ 0 \end{bmatrix} \\ & + (2\dot{r} \dot{\phi} + r\ddot{\phi}) \begin{bmatrix} \cos \theta \cos \phi \\ \sin \theta \cos \phi \\ -\sin \phi \end{bmatrix} - r \sin \phi \dot{\theta}^2 \begin{bmatrix} \cos \theta \\ \sin \theta \\ 0 \end{bmatrix},\end{aligned}\quad (66)$$

but

$$\begin{aligned}\sin \phi \hat{\mathbf{r}} + \cos \phi \hat{\phi} &= \begin{bmatrix} \cos \theta \sin^2 \phi + \cos \theta \cos^2 \phi \\ \sin \theta \sin^2 \phi + \sin \theta \cos^2 \phi \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} \cos \theta \\ \sin \theta \\ 0 \end{bmatrix},\end{aligned}\quad (67)$$

so

$$\begin{aligned}\ddot{\mathbf{r}} = & (\ddot{r} - r\dot{\phi}^2) \hat{\mathbf{r}} + (2r \cos \phi \dot{\theta} \dot{\phi} + 2 \sin \phi \dot{\theta} \dot{r} + r \sin \phi \ddot{\theta}) \hat{\theta} \\ & + (2\dot{r} \dot{\phi} + r\ddot{\phi}) \hat{\phi} - r \sin \phi \dot{\theta}^2 (\sin \phi \hat{\mathbf{r}} + \cos \phi \hat{\phi}) \\ = & (\ddot{r} - r\dot{\phi}^2 - r \sin^2 \phi \dot{\theta}^2) \hat{\mathbf{r}} \\ & + (2 \sin \phi \dot{\theta} \dot{r} + 2r \cos \phi \dot{\theta} \dot{\phi} + r \sin \phi \ddot{\theta}) \hat{\theta} \\ & + (2\dot{r} \dot{\phi} + r\ddot{\phi} - r \sin \phi \cos \phi \dot{\theta}^2) \hat{\phi}.\end{aligned}\quad (68)$$

Time DERIVATIVES of the UNIT VECTORS are

$$\dot{\hat{\mathbf{r}}} = \begin{bmatrix} -\sin \theta \sin \phi \dot{\theta} + \cos \theta \cos \phi \dot{\phi} \\ \cos \theta \sin \phi \dot{\theta} + \sin \theta \cos \phi \dot{\phi} \\ -\sin \phi \dot{\phi} \end{bmatrix} = \sin \phi \dot{\theta} \hat{\theta} + \dot{\phi} \hat{\phi}\quad (69)$$

$$\dot{\hat{\theta}} = \begin{bmatrix} -\cos \theta \dot{\theta} \\ -\sin \theta \dot{\theta} \\ 0 \end{bmatrix} = -\dot{\theta} \begin{bmatrix} \cos \theta \\ \sin \theta \\ 0 \end{bmatrix} = -\dot{\theta} (\sin \phi \hat{\mathbf{r}} + \cos \phi \hat{\phi})\quad (70)$$

$$\dot{\hat{\phi}} = \begin{bmatrix} -\sin \theta \cos \phi \dot{\theta} - \cos \theta \sin \phi \dot{\phi} \\ \cos \theta \cos \phi \dot{\theta} - \sin \theta \sin \phi \dot{\phi} \\ -\cos \phi \dot{\phi} \end{bmatrix} = -\dot{\phi} \hat{\mathbf{r}} + \cos \phi \dot{\theta} \hat{\theta}.\quad (71)$$

The CURL is

$$\begin{aligned}\nabla \times \mathbf{F} &= \frac{1}{r \sin \phi} \left[ \frac{\partial}{\partial \phi} (\sin \phi F_{\theta}) - \frac{\partial F_{\phi}}{\partial \theta} \right] \hat{\mathbf{r}} \\ &+ \frac{1}{r} \left[ \frac{1}{\sin \phi} \frac{\partial F_r}{\partial \theta} - \frac{\partial}{\partial r} (r F_{\theta}) \right] \hat{\phi} + \frac{1}{r} \left[ \frac{\partial}{\partial r} (r F_{\phi}) - \frac{\partial F_r}{\partial \phi} \right] \hat{\theta}.\end{aligned}\quad (72)$$

The LAPLACIAN is

$$\begin{aligned}\nabla^2 &\equiv \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial}{\partial r} \right) + \frac{1}{r^2 \sin^2 \phi} \frac{\partial^2}{\partial \theta^2} \\ &+ \frac{1}{r^2 \sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial}{\partial \phi} \right) \\ = &\frac{1}{r^2} \left( r^2 \frac{\partial^2}{\partial r^2} + 2r \frac{\partial}{\partial r} \right) + \frac{1}{r^2 \sin^2 \phi} \frac{\partial^2}{\partial \theta^2} \\ &+ \frac{1}{r^2 \sin \phi} \left( \cos \phi \frac{\partial}{\partial \phi} + \sin \phi \frac{\partial^2}{\partial \phi^2} \right) \\ = &\frac{\partial^2}{\partial r^2} + \frac{2}{r} \frac{\partial}{\partial r} + \frac{1}{r^2 \sin^2 \phi} \frac{\partial^2}{\partial \theta^2} \\ &+ \frac{\cos \phi}{r^2 \sin \phi} \frac{\partial}{\partial \phi} + \frac{1}{r^2} \frac{\partial^2}{\partial \phi^2}.\end{aligned}\quad (73)$$

The vector LAPLACIAN is

$$\nabla^2 \mathbf{v} = \begin{bmatrix} \frac{1}{r} \frac{\partial^2 (rv_r)}{\partial r^2} + \frac{1}{r^2} \frac{\partial^2 v_r}{\partial \theta^2} + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 v_r}{\partial \phi^2} + \frac{\cot \theta}{r^2} \frac{\partial v_r}{\partial \theta} \\ - \frac{2}{r^2} \frac{\partial v_{\theta}}{\partial \theta} - \frac{2}{r^2 \sin \theta} \frac{\partial v_{\phi}}{\partial \phi} - \frac{2v_r}{r^2} - \frac{2 \cot \theta}{r^2} v_{\theta} \\ \frac{1}{r} \frac{\partial^2 (rv_{\theta})}{\partial r^2} + \frac{1}{r^2} \frac{\partial^2 v_{\theta}}{\partial \theta^2} + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 v_{\theta}}{\partial \phi^2} + \frac{\cot \theta}{r^2} \frac{\partial v_{\theta}}{\partial \theta} \\ - \frac{2}{r^2} \frac{2 \cot \theta}{r^2 \sin \theta} \frac{\partial v_{\phi}}{\partial \phi} + \frac{2}{r^2} \frac{\partial v_r}{\partial \theta} - \frac{v_{\theta}}{r^2 \sin^2 \theta} \\ \frac{1}{r} \frac{\partial^2 (rv_{\phi})}{\partial r^2} + \frac{1}{r^2} \frac{\partial^2 v_{\phi}}{\partial \theta^2} + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 v_{\phi}}{\partial \phi^2} + \frac{\cot \theta}{r^2} \frac{\partial v_{\phi}}{\partial \theta} \\ + \frac{2}{r^2} \frac{\partial v_r}{\partial \phi} + \frac{2 \cot \theta}{r^2 \sin \theta} \frac{\partial v_{\theta}}{\partial \phi} - \frac{v_{\phi}}{r^2 \sin^2 \theta} \end{bmatrix}.\quad (74)$$

To express PARTIAL DERIVATIVES with respect to Cartesian axes in terms of PARTIAL DERIVATIVES of the spherical coordinates,

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} r \cos \theta \sin \phi \\ r \sin \theta \sin \phi \\ r \cos \phi \end{bmatrix}\quad (75)$$

$$\begin{aligned}\begin{bmatrix} dx \\ dy \\ dz \end{bmatrix} &= \begin{bmatrix} \cos \theta \sin \phi dr - r \sin \theta \sin \phi d\theta + r \cos \theta \cos \phi d\phi \\ \sin \theta \sin \phi dr + r \sin \phi \cos \theta d\theta + r \sin \theta \cos \phi d\phi \\ \cos \phi dr - r \sin \phi d\phi \end{bmatrix} \\ &= \begin{bmatrix} \cos \theta \sin \phi & -r \sin \theta \sin \phi & r \cos \theta \cos \phi \\ \sin \theta \sin \phi & r \sin \phi \cos \theta & r \sin \theta \cos \phi \\ \cos \phi & 0 & -r \sin \phi \end{bmatrix} \begin{bmatrix} dr \\ d\theta \\ d\phi \end{bmatrix}.\end{aligned}\quad (76)$$

Upon inversion, the result is

$$\begin{bmatrix} dr \\ d\theta \\ d\phi \end{bmatrix} = \begin{bmatrix} \cos \theta \sin \phi & \sin \theta \sin \phi & \cos \phi \\ -\frac{\sin \theta}{r \sin \phi} & \frac{\cos \theta}{r \sin \phi} & 0 \\ \frac{\cos \theta \cos \phi}{r} & \frac{\sin \theta \cos \phi}{r} & -\frac{\sin \phi}{r} \end{bmatrix} \begin{bmatrix} dx \\ dy \\ dz \end{bmatrix}.\quad (77)$$

The Cartesian PARTIAL DERIVATIVES in spherical coordinates are therefore

$$\begin{aligned}\frac{\partial}{\partial x} &= \frac{\partial r}{\partial x} \frac{\partial}{\partial r} + \frac{\partial \theta}{\partial x} \frac{\partial}{\partial \theta} + \frac{\partial \phi}{\partial x} \frac{\partial}{\partial \phi} \\ &= \cos \theta \sin \phi \frac{\partial}{\partial r} - \frac{\sin \theta}{r \sin \phi} \frac{\partial}{\partial \theta} + \frac{\cos \theta \cos \phi}{r} \frac{\partial}{\partial \phi}\end{aligned}\quad (78)$$

$$\begin{aligned}\frac{\partial}{\partial y} &= \frac{\partial r}{\partial y} \frac{\partial}{\partial r} + \frac{\partial \theta}{\partial y} \frac{\partial}{\partial \theta} + \frac{\partial \phi}{\partial y} \frac{\partial}{\partial \phi} \\ &= \sin \theta \sin \phi \frac{\partial}{\partial r} + \frac{\cos \theta}{r \sin \phi} \frac{\partial}{\partial \theta} + \frac{\sin \theta \cos \phi}{r} \frac{\partial}{\partial \phi}\end{aligned}\quad (79)$$

$$\begin{aligned}\frac{\partial}{\partial z} &= \frac{\partial r}{\partial z} \frac{\partial}{\partial r} + \frac{\partial \theta}{\partial z} \frac{\partial}{\partial \theta} + \frac{\partial \phi}{\partial z} \frac{\partial}{\partial \phi} \\ &= \cos \phi \frac{\partial}{\partial r} - \frac{\sin \phi}{r} \frac{\partial}{\partial \theta}\end{aligned}\quad (80)$$

(Gasiorowicz 1974, pp. 167–168).

The HELMHOLTZ DIFFERENTIAL EQUATION is separable in spherical coordinates.

### Spherical Design

$X$  is a spherical  $t$ -design in  $E$  IFF it is possible to exactly determine the average value on  $E$  of any POLYNOMIAL  $f$  of degree at most  $t$  by sampling  $f$  at the points of  $X$ . In other words,

$$\frac{1}{\text{volume } E} \int_E f(\xi) d\xi = \frac{1}{|X|} \sum_{x \in X} f(x).$$

### Spherical Harmonic

The spherical harmonics  $Y_l^m(\theta, \phi)$  are the angular portion of the solution to LAPLACE'S EQUATION in SPHERICAL COORDINATES where azimuthal symmetry is not present. Some care must be taken in identifying the notational convention being used. In the below equations,  $\theta$  is taken as the azimuthal (longitudinal) coordinate, and  $\phi$  as the polar (latitudinal) coordinate (opposite the notation of Arfken 1985).

$$Y_l^m(\theta, \phi) \equiv \sqrt{\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!}} P_l^m(\cos \phi) e^{im\theta}, \quad (1)$$

where  $m = -l, -l+1, \dots, 0, \dots, l$  and the normalization is chosen such that

$$\int_0^{2\pi} \int_0^\pi Y_l^m Y_{l'}^{m'} \sin \phi d\phi d\theta = \int_0^{2\pi} \int_{-1}^1 Y_l^m Y_{l'}^{m'} d(\cos \phi) d\theta = \delta_{mm'} \delta_{ll'}, \quad (2)$$

where  $\delta_{mn}$  is the KRONECKER DELTA. Sometimes, the CONDON-SHORTLEY PHASE  $(-1)^m$  is prepended to the definition of the spherical harmonics.

Integrals of the spherical harmonics are given by

$$\int Y_{l_1}^{m_1} Y_{l_2}^{m_2} Y_{l_3}^{m_3} d\Omega = \sqrt{\frac{(2l_1+1)(2l_2+1)(2l_3+1)}{4\pi}} \times \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix}, \quad (3)$$

where  $\begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$  is a WIGNER 3j-SYMBOL (which is related to the CLEBSCH-GORDON COEFFICIENTS). The spherical harmonics obey

$$Y_l^{-l} = \frac{1}{2^l l!} \sqrt{\frac{(2l+1)!}{4\pi}} \sin^l \phi e^{-il\theta} \quad (4)$$

$$Y_l^0 = \sqrt{\frac{2l+1}{4\pi}} P_l(\cos \phi) \quad (5)$$

$$Y_l^{-m} = (-1)^m Y_l^{m*}, \quad (6)$$

where  $P_l(x)$  is a LEGENDRE POLYNOMIAL.

The above illustrations show  $|Y_l^m(\theta, \phi)|$  (top) and  $\Re[Y_l^m(\theta, \phi)]$  and  $\Im[Y_l^m(\theta, \phi)]$  (bottom). The first few spherical harmonics are

$$Y_0^0 = \frac{1}{2} \sqrt{\frac{1}{\pi}}$$

$$Y_1^{-1} = \frac{1}{2} \sqrt{\frac{3}{2\pi}} \sin \phi e^{-i\theta}$$

$$Y_1^0 = \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos \phi$$

$$Y_1^1 = -\frac{1}{2} \sqrt{\frac{3}{2\pi}} \sin \phi e^{i\theta}$$

$$Y_2^{-2} = \frac{1}{4} \sqrt{\frac{15}{2\pi}} \sin^2 \phi e^{-2i\theta}$$

$$Y_2^{-1} = \frac{1}{2} \sqrt{\frac{15}{2\pi}} \sin \phi \cos \phi e^{-i\theta}$$

$$Y_2^0 = \frac{1}{4} \sqrt{\frac{5}{\pi}} (3 \cos^2 \phi - 1)$$

$$Y_2^1 = -\frac{1}{2} \sqrt{\frac{15}{2\pi}} \sin \phi \cos \phi e^{i\theta}$$

$$Y_2^2 = \frac{1}{4} \sqrt{\frac{15}{2\pi}} \sin^2 \phi e^{2i\theta}$$

$$Y_3^{-3} = \frac{1}{8} \sqrt{\frac{35}{\pi}} \sin^3 \phi e^{-3i\theta}$$

$$Y_3^{-2} = \frac{1}{4} \sqrt{\frac{105}{2\pi}} \sin^2 \phi \cos \phi e^{-2i\theta}$$

$$Y_3^{-1} = \frac{1}{8} \sqrt{\frac{21}{\pi}} \sin \phi (5 \cos^2 \phi - 1) e^{-i\theta}$$

$$Y_3^0 = \frac{1}{4} \sqrt{\frac{7}{\pi}} (5 \cos^3 \phi - 3 \cos \phi)$$

$$Y_3^1 = -\frac{1}{8} \sqrt{\frac{21}{\pi}} \sin \phi (5 \cos^2 \phi - 1) e^{i\theta}$$

$$Y_3^2 = \frac{1}{4} \sqrt{\frac{105}{2\pi}} \sin^2 \phi \cos \phi e^{2i\theta}$$

$$Y_3^3 = -\frac{1}{8} \sqrt{\frac{35}{\pi}} \sin^3 \phi e^{3i\theta}$$

Written in terms of CARTESIAN COORDINATES,

$$e^{i\theta} = \frac{x + iy}{\sqrt{x^2 + y^2}} \quad (7)$$

$$\phi = \sin^{-1} \left( \sqrt{\frac{x^2 + y^2}{x^2 + y^2 + z^2}} \right) \quad (8)$$

$$= \cos^{-1} \left( \frac{z}{\sqrt{x^2 + y^2 + z^2}} \right), \quad (9)$$

so

$$Y_0^0 = \frac{1}{2} \frac{1}{\sqrt{\pi}} \quad (10)$$

$$Y_1^0 = \frac{1}{2} \sqrt{\frac{3}{\pi}} \frac{z}{\sqrt{x^2 + y^2 + z^2}} \quad (11)$$

$$Y_1^1 = -\frac{1}{2} \sqrt{\frac{3}{2\pi}} \frac{x + iy}{\sqrt{x^2 + y^2 + z^2}} \quad (12)$$

$$Y_2^0 = \frac{1}{4} \sqrt{\frac{5}{\pi}} \left( \frac{3z^2}{x^2 + y^2 + z^2} - 1 \right) \quad (13)$$

$$Y_2^1 = -\frac{1}{2} \sqrt{\frac{15}{2\pi}} \frac{z(x + iy)}{x^2 + y^2 + z^2} \quad (14)$$

$$Y_2^2 = \frac{1}{4} \sqrt{\frac{15}{2\pi}} \frac{(x + iy)^2}{x^2 + y^2 + z^2}. \quad (15)$$

These can be separated into their REAL and IMAGINARY PARTS

$$Y_l^{ms}(\theta, \phi) \equiv P_l^m(\cos \phi) \sin(m\theta) \quad (16)$$

$$Y_l^{mc}(\theta, \phi) \equiv P_l^m(\cos \phi) \cos(m\theta). \quad (17)$$

The ZONAL HARMONICS are defined to be those of the form

$$P_n^m(\cos \theta). \quad (18)$$

The TESSERAL HARMONICS are those of the form

$$\sin(m\phi) P_n^m(\cos \theta) \quad (19)$$

$$\cos(m\phi) P_n^m(\cos \theta) \quad (20)$$

for  $n \neq m$ . The SECTORIAL HARMONICS are of the form

$$\sin(m\phi) P_m^m(\cos \theta) \quad (21)$$

$$\cos(m\phi) P_m^m(\cos \theta). \quad (22)$$

The spherical harmonics form a COMPLETE ORTHONORMAL BASIS, so an arbitrary REAL function  $f(\theta, \phi)$  can be expanded in terms of COMPLEX spherical harmonics

$$f(\theta, \phi) \equiv \sum_{l=0}^{\infty} \sum_{m=-l}^l A_l^m Y_l^m(\theta, \phi), \quad (23)$$

or REAL spherical harmonics

$$f(\theta, \phi) \equiv \sum_{l=0}^{\infty} \sum_{m=0}^l [C_l^m Y_l^{mc}(\theta, \phi) \sin(m\theta) + S_l^m Y_l^{ms}(\theta, \phi)]. \quad (24)$$

#### Spherical Harmonic Addition Theorem

A FORMULA also known as the LEGENDRE ADDITION THEOREM which is derived by finding GREEN'S FUNCTIONS for the SPHERICAL HARMONIC expansion and equating them to the generating function for LEGENDRE POLYNOMIALS. When  $\gamma$  is defined by

$$\cos \gamma \equiv \cos \theta_1 \cos \theta_2 + \sin \theta_1 \sin \theta_2 \cos \phi_1 - \phi_2,$$

$$\begin{aligned} P_n(\cos \gamma) &= \frac{4\pi}{2n+1} \sum_{m=-n}^n (-1)^m Y_m^n(\theta_1, \phi_1) Y_{-m}^n(\theta_2, \phi_2) \\ &= \frac{4\pi}{2n+1} \sum_{m=-n}^n Y_m^n(\theta_1, \phi_1) Y_m^{n*}(\theta_2, \phi_2) \\ &= P_n(\cos \theta_1) P_n(\cos \theta_2) \\ &+ 2 \sum_{m=-n}^n \frac{(n-m)!}{(n+m)!} P_m^n(\cos \theta_1) P_m^n(\cos \theta_2) \cos[m(\phi_1 - \phi_2)]. \end{aligned}$$

## Spherical Harmonic Closure Relations

The sum of the absolute squares of the SPHERICAL HARMONICS  $Y_l^m(\theta, \phi)$  over all values of  $m$  is

$$\sum_{m=-l}^l |Y_l^m(\theta, \phi)|^2 = \frac{2l+1}{4\pi}.$$

The double sum over  $m$  and  $l$  is given by

$$\begin{aligned} \sum_{l=0}^{\infty} \sum_{m=-l}^l Y_l^m(\theta_1, \phi_1) Y_l^{m*}(\theta_2, \phi_2) \\ = \frac{1}{\sin \theta_1} \delta(\theta_1 - \theta_2) \delta(\phi_1 - \phi_2) \\ = \delta(\cos \theta_1 - \cos \theta_2) \delta(\phi_1 - \phi_2), \end{aligned}$$

where  $\delta(x)$  is the DELTA FUNCTION.

## Spherical Harmonic Tensor

A tensor defined in terms of the TENSORS which satisfy the DOUBLE CONTRACTION RELATION.

see also DOUBLE CONTRACTION RELATION, SPHERICAL HARMONIC

## Spherical Helix

The TANGENT INDICATRIX of a CURVE OF CONSTANT PRECESSION is a spherical helix. The equation of a spherical helix on a SPHERE with RADIUS  $r$  making an ANGLE  $\theta$  with the  $z$ -axis is

$$\begin{aligned} x(\psi) &= \frac{1}{2}r(1 + \cos \theta) \cos \psi \\ &\quad - \frac{1}{2}r(1 - \cos \theta) \cos \left( \frac{1 + \cos \theta}{1 - \cos \theta} \psi \right) \end{aligned} \quad (1)$$

$$\begin{aligned} y(\psi) &= \frac{1}{2}r(1 + \cos \theta) \sin \psi \\ &\quad - \frac{1}{2}r(1 - \cos \theta) \sin \left( \frac{1 + \cos \theta}{1 - \cos \theta} \psi \right) \end{aligned} \quad (2)$$

$$z(\psi) = r \sin \theta \cos \left( \frac{\cos \theta}{1 - \cos \theta} \psi \right). \quad (3)$$

The projection on the  $xy$ -plane is an EPICYCLOID with RADIUS

$$a = r \cos \theta \quad (4)$$

$$b = r \sin^2(\frac{1}{2}\theta). \quad (5)$$

see also HELIX, LOXODROME, SPHERICAL SPIRAL

## References

Schofield, P. D. "Curves of Constant Precession." *Amer. Math. Monthly* 102, 531–537, 1995.

## Spherical Point System

How can  $n$  points be distributed on a SPHERE such that they maximize the minimum distance between any pair of points? This is FEJES TÓTH'S PROBLEM.

see also FEJES TÓTH'S PROBLEM

## Spherical Polygon

A closed geometric figure on the surface of a SPHERE which is formed by the ARCS of GREAT CIRCLES. The spherical polygon is a generalization of the SPHERICAL TRIANGLE. If  $\theta$  is the sum of the RADIAN ANGLES of a spherical polygon on a SPHERE of RADIUS  $r$ , then the AREA is

$$S = [\theta - (n - 2)\pi]r^2.$$

see also GREAT CIRCLE, SPHERICAL TRIANGLE

## References

Beyer, W. H. *CRC Standard Mathematical Tables*, 28th ed. Boca Raton, FL: CRC Press, p. 131, 1987.

## Spherical Ring

A SPHERE with a CYLINDRICAL HOLE cut so that the centers of the CYLINDER and SPHERE coincide, also called a NAPKIN RING.

The volume of the entire CYLINDER is

$$V_{\text{cyl}} = \pi L R^2, \quad (1)$$

and the VOLUME of the upper segment is

$$V_{\text{seg}} = \frac{1}{6}\pi h(3R^2 + h^2), \quad (2)$$

where

$$R = \sqrt{r^2 - \frac{1}{4}L^2} \quad (3)$$

$$h = r - \frac{1}{2}L, \quad (4)$$

so the VOLUME removed upon drilling of a CYLINDRICAL hole is

$$\begin{aligned} V_{\text{rem}} &= V_{\text{cyl}} + 2V_{\text{seg}} = \pi[L R^2 + \frac{1}{3}h(3R^2 + h^2)] \\ &= \pi(L R^2 + h R^2 + \frac{1}{3}h^3) \\ &= \pi[L(r^2 - \frac{1}{4}L^2) + (r - \frac{1}{2}L)(r^2 - \frac{1}{4}L^2) \\ &\quad + \frac{1}{3}(r - \frac{1}{2}L)^3] \\ &= \pi[L r^2 - \frac{1}{4}L^3 + (r^3 - \frac{1}{2}r^2 L - \frac{1}{4}R L^2 + \frac{1}{8}L^3) \\ &\quad + \frac{1}{3}(r^3 - \frac{3}{2}r^2 L + \frac{3}{4}r L^2 - \frac{1}{8}L^3)] \\ &= \pi[\frac{4}{3}r^3 + (1 - \frac{1}{2} - \frac{1}{2})r^2 L + (-\frac{1}{4} + \frac{1}{4})R L^2 \\ &\quad + L^3(-\frac{1}{4} + \frac{1}{8} - \frac{1}{24})] \\ &= \frac{4}{3}\pi r^3 - \frac{1}{6}\pi L^3 = \frac{1}{6}\pi(8r^3 - L^3), \end{aligned} \quad (5)$$

so

$$V_{\text{left}} = V_{\text{sphere}} - V_{\text{rem}} = \frac{4}{3}\pi r^3 - \left(\frac{4}{3}\pi r^3 - \frac{1}{6}\pi L^3\right) = \frac{1}{6}\pi L^3. \quad (6)$$

### Spherical Sector

The VOLUME of a spherical sector, depicted above, is given by

$$V = \frac{2}{3}\pi R^2 h,$$

where  $h$  is the vertical height of the upper and lower curves.

see also CYLINDRICAL SEGMENT, SPHERE, SPHERICAL CAP, SPHERICAL SEGMENT, ZONE

#### References

Beyer, W. H. *CRC Standard Mathematical Tables*, 28th ed. Boca Raton, FL: CRC Press, p. 131, 1987.

### Spherical Segment

A spherical segment is the solid defined by cutting a SPHERE with a pair of PARALLEL PLANES. It can be thought of as a SPHERICAL CAP with the top truncated, and so it corresponds to a SPHERICAL FRUSTUM. The surface of the spherical segment (excluding the bases) is called a ZONE.

Call the RADIUS of the SPHERE  $R$  and the height of the segment (the distance from the plane to the top of SPHERE)  $h$ . Let the RADII of the lower and upper bases be denoted  $a$  and  $b$ , respectively. Call the distance from the center to the start of the segment  $d$ , and the height from the bottom to the top of the segment  $h$ . Call the

RADIUS parallel to the segment  $r$ , and the height above the center  $y$ . Then  $r^2 = R^2 - y^2$ ,

$$\begin{aligned} V &= \int_d^{d+h} \pi r^2 dy = \pi \int_d^{d+h} (R^2 - y^2) dy \\ &= \pi \left[ R^2 y - \frac{1}{3} y^3 \right]_d^{d+h} = \pi \left\{ R^2 h - \frac{1}{3} [(d+h)^3 - d^3] \right\} \\ &= \pi \left[ R^2 h - \frac{1}{3} (d^3 + 3d^2 h + 3hd + h^3 - d^3) \right] \\ &= \pi (R^2 h - d^2 h - h^2 d - \frac{1}{3} h^3) \\ &= \pi h (R^2 - d^2 - hd - \frac{1}{3} h^2). \end{aligned} \quad (1)$$

Using

$$a^2 = R^2 - d^2 \quad (2)$$

$$b^2 = R^2 - (d+h)^2 = R^2 - d^2 - 2dh - h^2, \quad (3)$$

gives

$$a^2 + b^2 = 2R^2 - 2d^2 - 2dh - h^2 \quad (4)$$

$$R^2 - d^2 - dh = \frac{1}{2}(a^2 + b^2 + h^2), \quad (5)$$

so

$$\begin{aligned} V &= \pi h \left[ \frac{1}{2}(a^2 + b^2 + h^2) - \frac{1}{3} h^2 \right] = \pi h \left( \frac{1}{2} a^2 + \frac{1}{2} b^2 + \frac{1}{6} h^2 \right) \\ &= \frac{1}{6} \pi h (3a^2 + 3b^2 + h^2). \end{aligned} \quad (6)$$

The surface area of the ZONE (which excludes the top and bottom bases) is given by

$$S = 2\pi R h. \quad (7)$$

#### References

Beyer, W. H. *CRC Standard Mathematical Tables*, 28th ed. Boca Raton, FL: CRC Press, p. 130, 1987.

### Spherical Shell

A generalization of an ANNULUS to 3-D. A spherical shell is the intersection of two concentric BALLS of differing RADII.

see also ANNULUS, BALL, CHORD, SPHERE, SPHERICAL HELIX

### Spherical Spiral

The path taken by a ship which travels from the south pole to the north pole of a SPHERE while keeping a fixed (but not RIGHT) ANGLE with respect to the meridians. The curve has an infinite number of loops since the separation of consecutive revolutions gets smaller and smaller near the poles. It is given by the parametric equations

$$x = \cos t \cos c$$

$$y = \sin t \cos c$$

$$z = -\sin c,$$

where

$$c \equiv \tan^{-1}(at)$$

and  $a$  is a constant.

see also MERCATOR PROJECTION, SEIFERT'S SPHERICAL SPIRAL

## Spherical Symmetry

Let  $\mathbf{A}$  and  $\mathbf{B}$  be constant VECTORS. Define

$$Q \equiv 3(\mathbf{A} \cdot \hat{\mathbf{r}})(\mathbf{B} \cdot \hat{\mathbf{r}}) - \mathbf{A} \cdot \mathbf{B}.$$

Then the average of  $Q$  over a spherically symmetric surface or volume is

$$\langle Q \rangle = \langle 3 \cos^2 \theta - 1 \rangle (\mathbf{A} \cdot \mathbf{B}) = 0,$$

since  $\langle 3 \cos^2 \theta - 1 \rangle = 0$  over the sphere.

## Spherical Tessellation

see TRIANGULAR SYMMETRY GROUP

## Spherical Triangle

A spherical triangle is a figure formed on the surface of a sphere by three great circular arcs intersecting pairwise in three vertices. The spherical triangle is the spherical analog of the planar TRIANGLE. Let a spherical triangle

have ANGLES  $\alpha$ ,  $\beta$ , and  $\gamma$  and RADIUS  $r$ . Then the AREA of the spherical triangle is

$$K = r^2[(\alpha + \beta + \gamma) - \pi].$$

The sum of the angles of a spherical triangle is between  $180^\circ$  and  $540^\circ$ . The amount by which it exceeds  $180^\circ$  is called the SPHERICAL EXCESS and is denoted  $E$  or  $\Delta$ .

The study of angles and distances of figures on a sphere is known as SPHERICAL TRIGONOMETRY.

see also COLUNAR TRIANGLE, GIRARD'S SPHERICAL EXCESS FORMULA, L'HUIER'S THEOREM, SPHERICAL POLYGON, SPHERICAL TRIGONOMETRY

## Spherical Trigonometry

Define a SPHERICAL TRIANGLE on the surface of a unit SPHERE, centered at a point  $O$ , with vertices  $A$ ,  $B$ , and  $C$ . Define ANGLES  $a \equiv \angle BOC$ ,  $b \equiv \angle COA$ , and  $c \equiv \angle AOB$ . Let the ANGLE between PLANES  $AOB$  and  $AOC$  be  $\alpha$ , the ANGLE between PLANES  $BOC$  and  $AOB$  be  $\beta$ , and the ANGLE between PLANES  $BOC$  and  $AOC$  be  $\gamma$ . Define the VECTORS

$$\mathbf{a} \equiv \overrightarrow{OA} \quad (1)$$

$$\mathbf{b} \equiv \overrightarrow{OB} \quad (2)$$

$$\mathbf{c} \equiv \overrightarrow{OC}. \quad (3)$$

Then

$$\begin{aligned} (\hat{\mathbf{a}} \times \hat{\mathbf{b}}) \cdot (\hat{\mathbf{a}} \times \hat{\mathbf{c}}) &= (|\hat{\mathbf{a}}| |\hat{\mathbf{b}}| \sin c)(|\hat{\mathbf{a}}| |\hat{\mathbf{c}}| \sin b) \cos \alpha \\ &= \sin b \sin c \cos \alpha. \end{aligned} \quad (4)$$

Equivalently,

$$\begin{aligned} (\hat{\mathbf{a}} \times \hat{\mathbf{b}}) \cdot (\hat{\mathbf{a}} \times \hat{\mathbf{c}}) &= \hat{\mathbf{a}} \cdot [\hat{\mathbf{b}} \times (\hat{\mathbf{a}} \times \hat{\mathbf{c}})] \\ &= \hat{\mathbf{a}} \cdot [\hat{\mathbf{a}}(\hat{\mathbf{b}} \cdot \hat{\mathbf{c}}) - \hat{\mathbf{c}}(\hat{\mathbf{a}} \cdot \hat{\mathbf{b}})] \\ &= (\hat{\mathbf{b}} \cdot \hat{\mathbf{c}}) - (\hat{\mathbf{a}} \cdot \hat{\mathbf{c}})(\hat{\mathbf{a}} \cdot \hat{\mathbf{b}}) \\ &= \cos a - \cos c \cos b. \end{aligned} \quad (5)$$

Since these two expressions are equal, we obtain the identity

$$\cos a = \cos b \cos c + \sin b \sin c \cos \alpha \quad (6)$$

The identity

$$\begin{aligned} \sin \alpha &= \frac{|(\hat{\mathbf{a}} \times \hat{\mathbf{b}}) \times (\hat{\mathbf{a}} \times \hat{\mathbf{c}})|}{|\hat{\mathbf{a}} \times \hat{\mathbf{b}}| |\hat{\mathbf{a}} \times \hat{\mathbf{c}}|} = -\frac{\hat{\mathbf{a}}[\hat{\mathbf{b}}, \hat{\mathbf{a}}, \hat{\mathbf{c}}] + \hat{\mathbf{b}}[\hat{\mathbf{a}}, \hat{\mathbf{a}}, \hat{\mathbf{c}}]}{\sin b \sin c} \\ &= \frac{[\hat{\mathbf{a}}, \hat{\mathbf{b}}, \hat{\mathbf{c}}]}{\sin b \sin c}, \end{aligned} \quad (7)$$

where  $[\mathbf{a}, \mathbf{b}, \mathbf{c}]$  is the SCALAR TRIPLE PRODUCT, gives a spherical analog of the LAW OF SINES,

$$\frac{\sin \alpha}{\sin a} = \frac{\sin \beta}{\sin b} = \frac{\sin \gamma}{\sin c} = \frac{6 \text{Vol}(OABC)}{\sin a \sin b \sin c}, \quad (8)$$

where  $\text{Vol}(OABC)$  is the VOLUME of the TETRAHEDRON. From (7) and (8), it follows that

$$\sin a \cos \beta = \cos b \sin c - \sin b \cos c \cos \alpha \quad (9)$$

$$\cos a \cos \gamma = \sin a \cot b - \sin \gamma \cot \beta. \quad (10)$$

These are the fundamental equalities of spherical trigonometry.

There are also spherical analogs of the LAW OF COSINES for the sides of a spherical triangle,

$$\cos a = \cos b \cos c + \sin b \sin c \cos A \quad (11)$$

$$\cos b = \cos c \cos a + \sin c \sin a \cos B \quad (12)$$

$$\cos c = \cos a \cos b + \sin a \sin b \cos C, \quad (13)$$

and the angles of a spherical triangle,

$$\cos A = -\cos B \cos C + \sin B \sin C \cos a \quad (14)$$

$$\cos B = -\cos C \cos A + \sin C \sin A \cos b \quad (15)$$

$$\cos C = -\cos A \cos B + \sin A \sin B \cos c \quad (16)$$

(Beyer 1987), as well as the LAW OF TANGENTS

$$\frac{\tan[\frac{1}{2}(a-b)]}{\tan[\frac{1}{2}(a+b)]} = \frac{\tan[\frac{1}{2}(A-B)]}{\tan[\frac{1}{2}(A+B)]}. \quad (17)$$

Let

$$s \equiv \frac{1}{2}(a+b+c) \quad (18)$$

$$S \equiv \frac{1}{2}(A+B+C), \quad (19)$$

then the half-angle formulas are

$$\tan(\frac{1}{2}A) = \frac{k}{\sin(s-a)} \quad (20)$$

$$\tan(\frac{1}{2}B) = \frac{k}{\sin(s-b)} \quad (21)$$

$$\tan(\frac{1}{2}C) = \frac{k}{\sin(s-c)}, \quad (22)$$

where

$$k^2 = \frac{\sin(s-a) \sin(s-b) \sin(s-c)}{\sin s} = \tan^2 r, \quad (23)$$

and the half-side formulas are

$$\tan(\frac{1}{2}a) = K \cos(S-A) \quad (24)$$

$$\tan(\frac{1}{2}b) = K \cos(S-B) \quad (25)$$

$$\tan(\frac{1}{2}c) = K \cos(S-C), \quad (26)$$

where

$$K^2 = -\frac{\cos S}{(\cos(S-A) \cos(S-B) \cos(S-C))} = \tan^2 R, \quad (27)$$

where  $R$  is the RADIUS of the SPHERE on which the spherical triangle lies.

Additional formulas include the HAVERSINE formulas

$$\text{hav } a = \text{hav}(b-c) + \sin b \sin c \sin(s-c) \quad (28)$$

$$\text{hav } A = \frac{\sin(s-b) \sin(s-c)}{\sin b \sin c} \quad (29)$$

$$= \frac{\text{hav } a - \text{hav}(b-c)}{\sin b \sin c} \quad (30)$$

$$= \text{hav}[\pi - (B+C)] + \sin B \sin C \text{hav } a, \quad (31)$$

#### GAUSS'S FORMULAS

$$\frac{\sin[\frac{1}{2}(a-b)]}{\sin(\frac{1}{2}c)} = \frac{\sin[\frac{1}{2}(A-B)]}{\cos(\frac{1}{2}C)} \quad (32)$$

$$\frac{\sin[\frac{1}{2}(a+b)]}{\sin(\frac{1}{2}c)} = \frac{\cos[\frac{1}{2}(A-B)]}{\sin(\frac{1}{2}C)} \quad (33)$$

$$\frac{\cos[\frac{1}{2}(a-b)]}{\cos(\frac{1}{2}c)} = \frac{\sin[\frac{1}{2}(A+B)]}{\cos(\frac{1}{2}C)} \quad (34)$$

$$\frac{\cos[\frac{1}{2}(a+b)]}{\cos(\frac{1}{2}c)} = \frac{\cos[\frac{1}{2}(A+B)]}{\sin(\frac{1}{2}C)}, \quad (35)$$

#### and NAPIER'S ANALOGIES

$$\frac{\sin[\frac{1}{2}(A-B)]}{\sin[\frac{1}{2}(A+B)]} = \frac{\tan[\frac{1}{2}(a-b)]}{\tan(\frac{1}{2}c)} \quad (36)$$

$$\frac{\cos[\frac{1}{2}(A-B)]}{\cos[\frac{1}{2}(A+B)]} = \frac{\tan[\frac{1}{2}(a+b)]}{\tan(\frac{1}{2}c)} \quad (37)$$

$$\frac{\sin[\frac{1}{2}(a-b)]}{\sin[\frac{1}{2}(a+b)]} = \frac{\tan[\frac{1}{2}(A-B)]}{\cot(\frac{1}{2}C)} \quad (38)$$

$$\frac{\cos[\frac{1}{2}(a-b)]}{\cos[\frac{1}{2}(a+b)]} = \frac{\tan[\frac{1}{2}(A+B)]}{\cot(\frac{1}{2}C)} \quad (39)$$

(Beyer 1987).

## Spherical Vector Harmonic

see VECTOR SPHERICAL HARMONIC

## Spheroid

A spheroid is an ELLIPSOID

$$\frac{r^2 \cos^2 \theta \sin^2 \phi}{a^2} + \frac{r^2 \sin^2 \theta \sin^2 \phi}{b^2} + \frac{r^2 \cos^2 \phi}{c^2} = 1 \quad (1)$$

with two SEMIMAJOR AXES equal. Orient the ELLIPSE so that the  $a$  and  $b$  axes are equal, then

$$\frac{r^2 \cos^2 \theta \sin^2 \phi}{a^2} + \frac{r^2 \sin^2 \theta \sin^2 \phi}{a^2} + \frac{r^2 \cos^2 \phi}{c^2} = 1 \quad (2)$$

$$\frac{r^2 \sin^2 \phi}{a^2} + \frac{r^2 \cos^2 \phi}{c^2} = 1, \quad (3)$$

where  $a$  is the equatorial RADIUS and  $c$  is the polar RADIUS. Here  $\phi$  is the colatitude, so take  $\delta \equiv \pi/2 - \phi$  to express in terms of latitude.

$$\frac{r^2 \cos^2 \delta}{a^2} + \frac{r^2 \sin^2 \delta}{c^2} = 1. \quad (4)$$

Rewriting  $\cos^2 \delta = 1 - \sin^2 \delta$  gives

$$\frac{r^2}{a^2} + r^2 \sin^2 \delta \left( \frac{1}{c^2} - \frac{1}{a^2} \right) = 1 \quad (5)$$

$$\begin{aligned} r^2 \left( 1 + a^2 \sin^2 \delta \frac{a^2 - c^2}{c^2 a^2} \right) \\ = r^2 \left( 1 + \sin^2 \delta \frac{a^2 - c^2}{c^2} \right) = a^2, \end{aligned} \quad (6)$$

so

$$r = a \left( 1 + \sin^2 \delta \frac{a^2 - c^2}{c^2} \right)^{-1/2} \quad (7)$$

If  $a > c$ , the spheroid is OBLATE. If  $a < c$ , the spheroid is PROLATE. If  $a = c$ , the spheroid degenerates to a SPHERE.

see also DARWIN-DE SITTER SPHEROID, ELLIPSOID, OBLATE SPHEROID, PROLATE SPHEROID

## Spheroidal Harmonic

A spheroidal harmonic is a special case of the ELLIPSOIDAL HARMONIC which satisfies the differential equation

$$\frac{d}{dx} \left[ (1 - x^2) \frac{dS}{dx} \right] + \left( \lambda - c^2 x^2 - \frac{m^2}{1 - x^2} \right) S = 0$$

on the interval  $-1 \leq x \leq 1$ .

see also ELLIPSOIDAL HARMONIC

## Spider and Fly Problem

In a rectangular room (a CUBOID) with dimensions  $30' \times 12' \times 12'$ , a spider is located in the middle of one  $12' \times 12'$  wall one foot away from the ceiling. A fly is in the middle of the opposite wall one foot away from the floor. If the fly remains stationary, what is the shortest distance the spider must crawl to capture the fly? The answer,  $40'$ , can be obtained by "flattening" the walls as illustrated above.

## Spiric Section

A curve with Cartesian equation

$$(r^2 - a^2 + c^2 + x^2 + y^2) = 4r^2(x^2 + c^2).$$

Around 150 BC, Menaechmus constructed CONIC SECTIONS by cutting a CONE by a PLANE. Two hundred years later, the Greek mathematician Perseus investigated the curves obtained by cutting a TORUS by a PLANE which is PARALLEL to the line through the center of the HOLE of the TORUS (MacTutor).

In the FORMULA of the curve given above, the TORUS is formed from a CIRCLE of RADIUS  $a$  whose center is rotated along a CIRCLE of RADIUS  $r$ . The value of  $c$  gives the distance of the cutting PLANE from the center of the TORUS.

When  $c = 0$ , the curve consists of two CIRCLES of RADIUS  $a$  whose centers are at  $(r, 0)$  and  $(-r, 0)$ . If  $c = r + a$ , the curve consists of one point (the origin), while if  $c > r + a$ , no point lies on the curve. The above curves have  $(a, b, r) = (3, 4, 2), (3, 1, 2), (3, 0.8, 2), (3, 1, 4), (3, 1, 4.5),$  and  $(3, 0, 4.5)$ .

## Spirograph

A HYPOTROCHOID generated by a fixed point on a CIRCLE rolling inside a fixed CIRCLE. It has parametric equations,

$$x = (R + r) \cos \theta - (r + \rho) \cos \left( \frac{R + r}{r} \theta \right) \quad (1)$$

$$y = (R + r) \sin \theta - (r + \rho) \sin \left( \frac{R + r}{r} \theta \right), \quad (2)$$

where  $R$  is the radius of the fixed circle,  $r$  is the radius of the rotating circle, and  $\rho$  is the offset of the edge of the rotating circle. The figure closes only if  $R$ ,  $r$ , and  $\rho$  are RATIONAL. The equations can also be written

$$x = x_0[m \cos t + a \cos(nt)] - y_0[m \sin t - a \sin(nt)] \quad (3)$$

$$y = y_0[m \cos t + a \cos(nt)] + x_0[m \sin t - a \sin(nt)], \quad (4)$$

where the outer wheel has radius 1, the inner wheel a radius  $p/q$ , the pen is placed  $a$  units from the center, the beginning is at  $\theta$  radians above the  $x$ -axis, and

$$m \equiv \frac{q-p}{q} \quad (5)$$

$$n \equiv \frac{q-p}{p} \quad (6)$$

$$x_0 \equiv \cos \theta \quad (7)$$

$$y_0 \equiv \sin \theta. \quad (8)$$

The following curves are for  $a = i/10$ , with  $i = 1, 2, \dots, 10$ , and  $\theta = 0$ .

$(p, q) = (1, 3)$

$(p, q) = (1, 4)$

$(p, q) = (1, 5)$

$(p, q) = (2, 5)$

$(p, q) = (2, 7)$

$(p, q) = (3, 7)$

Additional attractive designs such as the following can also be made by superposing individual spirographs.

see also EPITROCHOID, HYPOTROCHOID, MAURER ROSE, SPIROLATERAL

### Spirolateral

A figure formed by taking a series of steps of length 1, 2,  $\dots$ ,  $n$ , with an angle  $\theta$  turn after each step. The symbol for a spirolateral is  $a_1 \dots a_n \theta$ , where the  $a_i$ s indicate that turns are in the  $-\theta$  direction for these steps.

 $2_{60}$  $6_{90}$

**Sporadic Group**

One of the 26 finite SIMPLE GROUPS. The most complicated is the MONSTER GROUP. A summary, as given by Conway *et al.* (1985), is given below.

Sym	Name	Order	M	A
$M_{11}$	Mathieu	$2^4 \cdot 3^2 \cdot 5 \cdot 11$	1	1
$M_{12}$	Mathieu	$2^6 \cdot 3^3 \cdot 5 \cdot 11$	2	2
$M_{22}$	Mathieu	$2^7 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11$	12	2
$M_{23}$	Mathieu	$2^7 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11 \cdot 23$	1	1
$M_{24}$	Mathieu	$2^{10} \cdot 3^3 \cdot 5 \cdot 7 \cdot 11 \cdot 23$	1	1
$J_2 = HJ$	Janko	$2^7 \cdot 3^3 \cdot 5^2 \cdot 7$	2	2
$Suz$	Suzuki	$2^{13} \cdot 3^7 \cdot 5^2 \cdot 7 \cdot 11 \cdot 13$	6	2
$HS$	Higman-Sims	$2^9 \cdot 3^2 \cdot 5^3 \cdot 7 \cdot 11$	2	2
$McL$	McLaughlin	$2^7 \cdot 3^6 \cdot 5^3 \cdot 7 \cdot 11$	3	2
$Co_3$	Conway	$2^{10} \cdot 3^7 \cdot 5^3 \cdot 7 \cdot 11 \cdot 23$	1	1
$Co_2$	Conway	$2^{18} \cdot 3^6 \cdot 5^3 \cdot 7 \cdot 11 \cdot 23$	1	1
$Co_1$	Conway	$2^{21} \cdot 3^9 \cdot 5^4 \cdot 7^2 \cdot 11 \cdot 13 \cdot 23$	2	1
$He$	Held	$2^{10} \cdot 3^3 \cdot 5^2 \cdot 7^3 \cdot 17$	1	2
$Fi_{22}$	Fischer	$2^{17} \cdot 3^9 \cdot 5^2 \cdot 7 \cdot 11 \cdot 13$	6	2
$Fi_{23}$	Fischer	$2^{18} \cdot 3^{13} \cdot 5^2 \cdot 7 \cdot 11 \cdot 13 \cdot 17 \cdot 23$	1	1
$Fi'_{24}$	Fischer	$2^{21} \cdot 3^{16} \cdot 5^2 \cdot 7^3 \cdot 11 \cdot 13 \cdot 17$ $\cdot 23 \cdot 29$	3	2
$HN$	Harada-Norton	$2^{14} \cdot 3^6 \cdot 5^6 \cdot 7 \cdot 11 \cdot 19$	1	2
$Th$	Thompson	$2^{15} \cdot 3^{10} \cdot 5^3 \cdot 7^2 \cdot 13 \cdot 19 \cdot 31$	1	1
$B$	Baby Monster	$2^{41} \cdot 3^{13} \cdot 5^6 \cdot 7^2 \cdot 11 \cdot 13 \cdot 17 \cdot 19$ $\cdot 23 \cdot 31 \cdot 47$	2	1
$M$	Monster	$2^{46} \cdot 3^{20} \cdot 5^9 \cdot 7^6 \cdot 11^2 \cdot 13^3 \cdot 17 \cdot 19$ $\cdot 23 \cdot 29 \cdot 31 \cdot 41 \cdot 47 \cdot 59 \cdot 71$	1	1
$J_1$	Janko	$2^3 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot 19$	1	1
$O'N$	O'Nan	$2^9 \cdot 3^4 \cdot 7^3 \cdot 5 \cdot 11 \cdot 19 \cdot 31$	3	2
$J_3$	Janko	$2^7 \cdot 3^5 \cdot 5 \cdot 17 \cdot 19$	3	2
$Ly$	Lyons	$2^8 \cdot 3^7 \cdot 5^6 \cdot 7 \cdot 11 \cdot 31 \cdot 37 \cdot 67$	1	1
$Ru$	Rudvalis	$2^{14} \cdot 3^3 \cdot 5^3 \cdot 7 \cdot 13 \cdot 29$	2	1
$J_4$	Janko	$2^{21} \cdot 3^3 \cdot 5 \cdot 7 \cdot 11^3 \cdot 23 \cdot 29 \cdot 31$ $\cdot 37 \cdot 43$	1	1

**Spun Knot**

A 3-D KNOT spun about a plane in 4-D. Unlike SUSPENDED KNOTS, spun knots are smoothly embedded at the poles.

see also SUSPENDED KNOT, TWIST-SPUN KNOT

**Squarable**

An object which can be constructed by SQUARING is called squarable.

**Square**

The term square is sometimes used to mean SQUARE NUMBER. When used in reference to a geometric figure, however, it means a convex QUADRILATERAL with four equal sides at RIGHT ANGLES to each other, illustrated above.

The PERIMETER of a square with side length  $a$  is

$$L = 4a \quad (1)$$

and the AREA is

$$A = a^2. \quad (2)$$

The INRADIUS  $r$ , CIRCUMRADIUS  $R$ , and AREA  $A$  can be computed directly from the formulas for a general regular POLYGON with side length  $a$  and  $n = 4$  sides,

$$r = \frac{1}{2}a \cot\left(\frac{\pi}{4}\right) = \frac{1}{2}a \quad (3)$$

$$R = \frac{1}{2}a \csc\left(\frac{\pi}{4}\right) = \frac{1}{2}\sqrt{2}a \quad (4)$$

$$A = \frac{1}{4}na^2 \cot\left(\frac{\pi}{4}\right) = a^2. \quad (5)$$

The length of the DIAGONAL of the UNIT SQUARE is  $\sqrt{2}$ , sometimes known as PYTHAGORAS'S CONSTANT.

The AREA of a square inscribed inside a UNIT SQUARE as shown in the above diagram can be found as follows. Label  $x$  and  $y$  as shown, then

$$x^2 + y^2 = r^2 \quad (6)$$

$$(\sqrt{1+r^2} - x)^2 + y^2 = 1. \quad (7)$$

Plugging (6) into (7) gives

$$(\sqrt{1+r^2} - x)^2 + (r^2 - x^2) = 1. \quad (8)$$

Expanding

$$x^2 - 2x\sqrt{1+r^2} + 1 + r^2 + r^2 - x^2 = 1 \quad (9)$$

and solving for  $x$  gives

$$x = \frac{r^2}{\sqrt{1+r^2}}. \quad (10)$$

Plugging in for  $y$  yields

$$y = \sqrt{r^2 - x^2} = \frac{r}{\sqrt{1+r^2}}. \quad (11)$$

The area of the shaded square is then

$$A = (\sqrt{1+r^2} - x - y)^2 = \frac{(1-r)^2}{1+r^2} \quad (12)$$

(Detemple and Harold 1996).

The STRAIGHTEDGE and COMPASS construction of the square is simple. Draw the line  $OP_0$  and construct a circle having  $OP_0$  as a radius. Then construct the perpendicular  $OB$  through  $O$ . Bisect  $P_0OB$  and  $P'_0OB$  to locate  $P_1$  and  $P_2$ , where  $P'_0$  is opposite  $P_0$ . Similarly,

construct  $P_3$  and  $P_4$  on the other SEMICIRCLE. Connecting  $P_1P_2P_3P_4$  then gives a square.

As shown by Schnirelmann, a square can be INSCRIBED in any closed convex planar curve (Steinhaus 1983). A square can also be CIRCUMSCRIBED about any closed curve (Steinhaus 1983).

An infinity of points in the interior of a square are known whose distances from three of the corners of a square are RATIONAL NUMBERS. Calling the distances  $a$ ,  $b$ , and  $c$  where  $s$  is the side length of the square, these solutions satisfy

$$(s^2 + b^2 - a^2)^2 + (s^2 + b^2 - c^2)^2 = (2bs)^2 \quad (13)$$

(Guy 1994). In this problem, one of  $a$ ,  $b$ ,  $c$ , and  $s$  is DIVISIBLE by 3, one by 4, and one by 5. It is not known if there are points having distances from *all four* corners RATIONAL, but such a solution requires the additional condition

$$a^2 + c^2 = b^2 + d^2. \quad (14)$$

In this problem,  $s$  is DIVISIBLE by 4 and  $a$ ,  $b$ ,  $c$ , and  $d$  are ODD. If  $s$  is not DIVISIBLE by 3 (5), then two of  $a$ ,  $b$ ,  $c$ , and  $d$  are DIVISIBLE by 3 (5) (Guy 1994).

The GRANNY KNOT has the same ALEXANDER POLYNOMIAL  $(x^2 - x + 1)^2$  as the square knot. The square knot is also called the REEF KNOT.*see also* GRANNY KNOT, MIRROR IMAGE, TREFOIL KNOT**References**Owen, P. *Knots*. Philadelphia, PA: Courage, p. 50, 1993.**Square Matrix**A MATRIX for which horizontal and vertical dimensions are the same (i.e., an  $n \times n$  MATRIX).*see also* MATRIX**Square Number**A FIGURATE NUMBER of the form  $m = n^2$ , where  $n$  is an INTEGER. A square number is also called a PERFECT SQUARE. The first few square numbers are 1, 4, 9, 25, 36, 49, ... (Sloane's A000290). The GENERATING FUNCTION giving the square numbers is

$$\frac{x(x+1)}{(1-x)^3} = x + 4x^2 + 9x^3 + 16x^4 + \dots \quad (1)$$

The  $k$ th nonsquare number  $a_k$  is given by

$$a_n = n + \left\lfloor \frac{1}{2} + \sqrt{n} \right\rfloor, \quad (2)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, and the first few are 2, 3, 5, 6, 7, 8, 10, 11, ... (Sloane's A000037).The only numbers which are simultaneously square and PYRAMIDAL (the CANNONBALL PROBLEM) are  $P_1 = 1$  and  $P_{24} = 4900$ , corresponding to  $S_1 = 1$  and  $S_{70} = 4900$  (Dickson 1952, p. 25; Ball and Coxeter 1987, p. 59; Ogilvy 1988), as conjectured by Lucas (1875, 1876) and proved by Watson (1918). The CANNONBALL PROBLEM is equivalent to solving the DIOPHANTINE EQUATION

$$y^2 = \frac{1}{6}x(x+1)(2x+1) \quad (3)$$

(Guy 1994, p. 147).

The only numbers which are square and TETRAHEDRAL are  $Te_1 = 1$ ,  $Te_2 = 4$ , and  $Te_{48} = 19600$  (giving  $S_1 = 1$ ,  $S_2 = 4$ , and  $S_{140} = 19600$ ), as proved by Meyl (1878; cited in Dickson 1952, p. 25; Guy 1994, p. 147). In general, proving that only certain numbers are simultaneously figurate in two different ways is far from elementary.

To find the possible last digits for a square number, write  $n = 10a + b$  for the number written in decimal NOTATION as  $ab_{10}$  ( $a, b = 0, 1, \dots, 9$ ). Then

$$n^2 = 100a^2 + 20ab + b^2, \quad (4)$$

so the last digit of  $n^2$  is the same as the last digit of  $b^2$ . The following table gives the last digit of  $b^2$  for  $b = 0, 1, \dots, 9$ . As can be seen, the last digit can be only 0, 1, 4, 5, 6, or 9.

0	1	2	3	4	5	6	7	8	9
0	1	4	9	6	5	6	9	4	1

We can similarly examine the allowable last two digits by writing  $abc_{10}$  as

$$n = 100a + 10b + c, \quad (5)$$

so

$$\begin{aligned} n^2 &= (100a + 10b + c)^2 \\ &= 10^4 a^2 + 2(1000ab + 100ac + 10bc) + 100b^2 + c^2 \\ &= (10^4 a^2 + 2000ab + 100ac + 100b^2) + 20bc + c^2, \end{aligned} \quad (6)$$

so the last two digits are given by  $20bc + c^2 = c(20b + c)$ . But since the last digit must be 0, 1, 4, 5, 6, or 9, the following table exhausts all possible last two digits.

c	b									
	0	1	2	3	4	5	6	7	8	9
1	01	21	41	61	81	01	21	41	61	81
4	16	96	76	56	36	16	96	76	56	36
5	25	25	25	25	25	25	25	25	25	25
6	36	56	76	96	16	36	56	76	96	16
9	81	61	41	21	01	81	61	41	21	01

The only possibilities are 00, 01, 04, 09, 16, 21, 24, 25, 29, 36, 41, 44, 49, 56, 61, 64, 69, 76, 81, 84, 89, and 96, which can be summarized succinctly as 00,  $e1$ ,  $e4$ , 25,  $o6$ , and  $e9$ , where  $e$  stands for an EVEN NUMBER and  $o$  for an ODD NUMBER. Additionally, unless the sum of the digits of a number is 1, 4, 7, or 9, it cannot be a square number.

The following table gives the possible residues mod  $n$  for square numbers for  $n = 1$  to 20. The quantity  $s(n)$  gives the number of distinct residues for a given  $n$ .

$n$	$s(n)$	$x^2 \pmod{n}$
2	2	0, 1
3	2	0, 1
4	2	0, 1
5	3	0, 1, 4
6	4	0, 1, 3, 4
7	4	0, 1, 2, 4
8	3	0, 1, 4
9	4	0, 1, 4, 7
10	6	0, 1, 4, 5, 6, 9
11	6	0, 1, 3, 4, 5, 9
12	4	0, 1, 4, 9
13	7	0, 1, 3, 4, 9, 10, 12
14	8	0, 1, 2, 4, 7, 8, 9, 11
15	6	0, 1, 4, 6, 9, 10
16	4	0, 1, 4, 9
17	9	0, 1, 2, 4, 8, 9, 13, 15, 16
18	8	0, 1, 4, 7, 9, 10, 13, 16
19	10	0, 1, 4, 5, 6, 7, 9, 11, 16, 17
20	6	0, 1, 4, 5, 9, 16

In general, the ODD squares are congruent to 1 (mod 8) (Conway and Guy 1996). Stangl (1996) gives an explicit formula by which the number of squares  $s(n)$  in  $\mathbb{Z}_n$  (i.e., mod  $n$ ) can be calculated. Let  $p$  be an ODD PRIME. Then  $s(n)$  is the MULTIPLICATIVE FUNCTION given by

$$s(2) = 2 \quad (7)$$

$$s(p) = \frac{1}{2}(p+1) \quad (p \neq 2) \quad (8)$$

$$s(p^2) = \frac{1}{2}(p^2 - p + 2) \quad (p \neq 2) \quad (9)$$

$$s(2^n) = \begin{cases} \frac{1}{2}(2^{n-1} + 4) & \text{for } n \text{ even} \\ \frac{1}{2}(2^{n-1} + 5) & \text{for } n \text{ odd} \end{cases} \quad (10)$$

$$s(p^n) = \begin{cases} \frac{p^{n+1} + p + 2}{2(p+1)} & \text{for } n \geq 3 \text{ even} \\ \frac{p^{n+1} + 2p + 1}{2(p+1)} & \text{for } n \geq 3 \text{ odd.} \end{cases} \quad (11)$$

$s(n)$  is related to the number  $q(n)$  of QUADRATIC RESIDUES in  $\mathbb{Z}_n$  by

$$q(p^n) = s(p^n) - s(p^{n-2}) \quad (12)$$

for  $n \geq 3$  (Stangl 1996).

For a perfect square  $n$ ,  $(n/p) = 0$  or 1 for all ODD PRIMES  $p < n$  where  $(n/p)$  is the LEGENDRE SYMBOL. A number  $n$  which is not a perfect square but which satisfies this relationship is called a PSEUDOSQUARE.

The minimum number of squares needed to represent the numbers 1, 2, 3, ... are 1, 2, 3, 1, 2, 3, 4, 2, 1, 2, ... (Sloane's A002828), and the number of distinct ways to represent the numbers 1, 2, 3, ... in terms of squares are 1, 1, 1, 2, 2, 2, 2, 3, 4, 4, ... (Sloane's A001156). A brute-force algorithm for enumerating the square permutations of  $n$  is repeated application of the GREEDY ALGORITHM. However, this approach rapidly becomes impractical since the number of representations grows extremely rapidly with  $n$ , as shown in the following table.

$n$	Square Partitions
10	4
50	104
100	1116
150	6521
200	27482

Every POSITIVE integer is expressible as a SUM of (at most)  $g(2) = 4$  square numbers (WARING'S PROBLEM). (Actually, the basis set is  $\{0, 1, 4, 9, 16, 25, 36, 64, 81, 100, \dots\}$ , so 49 need never be used.) Furthermore, an infinite number of  $n$  require four squares to represent them, so the related quantity  $G(2)$  (the least INTEGER  $n$  such that every POSITIVE INTEGER beyond a certain point requires  $G(2)$  squares) is given by  $G(2) = 4$ .

Numbers expressible as the sum of two squares are those whose PRIME FACTORS are of the form  $4k - 1$  taken to an EVEN POWER. Numbers expressible as the sum of three squares are those not of the form  $4^k(8l + 7)$  for  $k, l \geq 0$ . The following table gives the first few numbers which require  $N = 1, 2, 3$ , and 4 squares to represent them as a sum.

$N$	Sloane	Numbers
1	000290	1, 4, 9, 16, 25, 36, 49, 64, 81, ...
2	000415	2, 5, 8, 10, 13, 17, 18, 20, 26, 29, ...
3	000419	3, 6, 11, 12, 14, 19, 21, 22, 24, 27, ...
4	004215	7, 15, 23, 28, 31, 39, 47, 55, 60, 63, ...

The FERMAT  $4n + 1$  THEOREM guarantees that every PRIME of the form  $4n + 1$  is a sum of two SQUARE NUMBERS in only one way.

There are only 31 numbers which cannot be expressed as the sum of *distinct* squares: 2, 3, 6, 7, 8, 11, 12, 15, 18, 19, 22, 23, 24, 27, 28, 31, 32, 33, 43, 44, 47, 48, 60, 67, 72, 76, 92, 96, 108, 112, 128 (Sloane's A001422; Guy 1994). All numbers  $> 188$  can be expressed as the sum of at most five distinct squares, and only

$$124 = 1 + 4 + 9 + 25 + 36 + 49 \quad (13)$$

and

$$188 = 1 + 4 + 9 + 25 + 49 + 100 \quad (14)$$

require six distinct squares (Bohman *et al.* 1979; Guy 1994, p. 136). In fact, 188 can also be represented using seven distinct squares:

$$188 = 1 + 4 + 9 + 25 + 36 + 49 + 64. \quad (15)$$

The following table gives the numbers which can be represented in  $W$  different ways as a sum of  $S$  squares. For example,

$$50 = 1^2 + 7^2 = 5^2 + 5^2$$

can be represented in two ways ( $W = 2$ ) by two squares ( $S = 2$ ).

$S$	$W$	Sloane	Numbers
1	1	000290	1, 4, 9, 16, 25, 36, 49, 64, 81, 100, ...
2	1	025284	2, 5, 8, 10, 13, 17, 18, 20, 25, 26, 29, ...
2	2	025285	50, 65, 85, 125, 130, 145, 170, 185, ...
3	1	025321	3, 6, 9, 11, 12, 14, 17, 18, 19, 21, 22, ...
3	2	025322	27, 33, 38, 41, 51, 57, 59, 62, 69, 74, ...
3	3	025323	54, 66, 81, 86, 89, 99, 101, 110, 114, ...
3	4	025324	129, 134, 146, 153, 161, 171, 189, ...
4	1	025357	4, 7, 10, 12, 13, 15, 16, 18, 19, 20, ...
4	2	025358	31, 34, 36, 37, 39, 43, 45, 47, 49, ...
4	3	025359	28, 42, 55, 60, 66, 67, 73, 75, 78, ...
4	4	025360	52, 58, 63, 70, 76, 84, 87, 91, 93, ...

The number of INTEGERS  $< x$  which are squares or sums of two squares is

$$N(x) \sim kx(\ln x)^{-1/2}, \quad (16)$$

where

$$k = \sqrt{\frac{1}{2} \prod_{\substack{r=4n+3 \\ r \text{ prime}}} (1 - r^{-2})^{-1}} \quad (17)$$

(Landau 1908; Le Lionnais 1983, p. 31). The product of four distinct NONZERO INTEGERS in ARITHMETIC PROGRESSION is square only for  $(-3, -1, 1, 3)$ , giving  $(-3)(-1)(1)(3) = 9$  (Le Lionnais 1983, p. 53). It is possible to have three squares in ARITHMETIC PROGRESSION, but not four (Dickson 1952, pp. 435–440). If these numbers are  $r^2$ ,  $s^2$ , and  $t^2$ , there are POSITIVE INTEGERS  $p$  and  $q$  such that

$$r = |p^2 - 2pq - q^2| \quad (18)$$

$$s = p^2 + q^2 \quad (19)$$

$$t = p^2 + 2pq - q^2, \quad (20)$$

where  $(p, q) = 1$  and one of  $r$ ,  $s$ , or  $t$  is EVEN (Dickson 1952, pp. 437–438). Every three-term progression of squares can be associated with a PYTHAGOREAN TRIPLE  $(X, Y, Z)$  by

$$X = \frac{1}{2}(r + t) \quad (21)$$

$$Y = \frac{1}{2}(t - r) \quad (22)$$

$$Z = s \quad (23)$$

(Robertson 1996).

CATALAN'S CONJECTURE states that 8 and 9 ( $2^3$  and  $3^2$ ) are the only consecutive POWERS (excluding 0 and 1), i.e., the only solution to CATALAN'S DIOPHANTINE PROBLEM. This CONJECTURE has not yet been proved or refuted, although R. Tijdeman has proved that there can be only a finite number of exceptions should the CONJECTURE not hold. It is also known that 8 and 9 are the only consecutive CUBIC and square numbers (in either order).

A square number can be the concatenation of two squares, as in the case  $16 = 4^2$  and  $9 = 3^2$  giving  $169 = 13^2$ .

It is conjectured that, other than  $10^{2n}$ ,  $4 \times 10^{2n}$  and  $9 \times 10^{2n}$ , there are only a FINITE number of squares  $n^2$  having exactly two distinct NONZERO DIGITS (Guy 1994, p. 262). The first few such  $n$  are 4, 5, 6, 7, 8, 9, 11, 12, 15, 21, ... (Sloane's A016070), corresponding to  $n^2$  of 16, 25, 36, 49, 64, 81, 121, ... (Sloane's A016069).

The following table gives the first few numbers which, when squared, give numbers composed of only certain digits. The only known square number composed only of the digits 7, 8, and 9 is 9. Vardi (1991) considers numbers composed only of the square digits: 1, 4, and 9.

Digits	Sloane	$n, n^2$
1, 2, 3	030175	1, 11, 111, 36361, 363639, ...
	030174	1, 121, 12321, 132212321, ...
1, 4, 6	027677	1, 2, 4, 8, 12, 31, 38, 108, ...
	027676	1, 4, 16, 64, 144, 441, 1444, ...
1, 4, 9	027675	1, 2, 3, 7, 12, 21, 38, 107, ...
	006716	1, 4, 9, 49, 144, 441, 1444, 11449, ...
2, 4, 8	027679	2, 22, 168, 478, 2878, 210912978, ...
	027678	4, 484, 28224, 228484, 8282884, ...
4, 5, 6	030177	2, 8, 216, 238, 258, 738, 6742, ...
	030176	4, 64, 46656, 56644, 66564, ...

BROWN NUMBERS are pairs  $(m, n)$  of INTEGERS satisfying the condition of BROCARD'S PROBLEM, i.e., such that

$$n! + 1 = m^2, \quad (24)$$

where  $n!$  is a FACTORIAL. Only three such numbers are known: (5,4), (11,5), (71,7). Erdős conjectured that these are the only three such pairs.

Either  $5x^2 + 4 = y^2$  or  $5x^2 - 4 = y^2$  has a solution in POSITIVE INTEGERS IFF, for some  $n$ ,  $(x, y) = (F_n, L_n)$ , where  $F_n$  is a FIBONACCI NUMBER and  $L_n$  is a LUCAS NUMBER (Honsberger 1985, pp. 114–118).

The smallest and largest square numbers containing the digits 1 to 9 are

$$11,826^2 = 139,854,276, \quad (25)$$

$$30,384^2 = 923,187,456. \quad (26)$$

The smallest and largest square numbers containing the digits 0 to 9 are

$$32,043^2 = 1,026,753,849, \quad (27)$$

$$99,066^2 = 9,814,072,356 \quad (28)$$

(Madachy 1979, p. 159). The smallest and largest square numbers containing the digits 1 to 9 twice each are

$$335,180,136^2 = 112,345,723,568,978,496 \quad (29)$$

$$999,390,432^2 = 998,781,235,573,146,624, \quad (30)$$

and the smallest and largest containing 1 to 9 three times are

$$10,546,200,195,312^2 = 111,222,338,559,598,866,946,777,344 \quad (31)$$

$$31,621,017,808,182^2 = 999,888,767,225,363,175,346,145,124 \quad (32)$$

(Madachy 1979, p. 159).

Madachy (1979, p. 165) also considers number which are equal to the sum of the squares of their two "halves" such as

$$1233 = 12^2 + 33^2 \quad (33)$$

$$8833 = 88^2 + 33^2 \quad (34)$$

$$10100 = 10^2 + 100^2 \quad (35)$$

$$5882353 = 588^2 + 2353^2, \quad (36)$$

in addition to a number of others.

### Square Packing

Find the minimum size SQUARE capable of bounding  $n$  equal SQUARES arranged in any configuration. The only packings which have been proven optimal are 2, 3, 5, and SQUARE NUMBERS (4, 9, ...). If  $n = a^2 - a$  for some  $a$ , it is CONJECTURED that the size of the minimum bounding square is  $a$  for small  $n$ . The smallest  $n$  for which the CONJECTURE is known to be violated is 1560. The size is known to scale as  $k^b$ , where

$$\frac{1}{2}(3 - \sqrt{3}) < b < \frac{1}{2}.$$

see also L-POLYOMINO, SKEW POLYOMINO, STRAIGHT POLYOMINO, T-POLYOMINO

### Square Pyramid

A square pyramid is a PYRAMID with a SQUARE base. If the top of the pyramid is cut off by a PLANE, a square PYRAMIDAL FRUSTUM is obtained. If the four TRIANGLES of the square pyramid are EQUILATERAL, the square pyramid is the "regular" POLYHEDRON known as JOHNSON SOLID  $J_1$  and, for side length  $a$ , has height

$$h = \frac{1}{2}\sqrt{2}a. \quad (1)$$

Using the equation for a general PYRAMID, the VOLUME of the "regular" is therefore

$$V = \frac{1}{3}hA_b = \frac{1}{6}\sqrt{2}a^3. \quad (2)$$

If the apex of the pyramid does not lie atop the center of the base, then the SLANT HEIGHT is given by

$$s = \sqrt{h^2 + \frac{1}{2}a^2}, \quad (3)$$

where  $h$  is the height and  $a$  is the length of a side of the base.

Consider a HEMISPHERE placed on the base of a square pyramid (having side lengths  $a$  and height  $h$ ). Further, let the hemisphere be tangent to the four apex edges. Then what is the volume of the HEMISPHERE which is interior the pyramid (Cipra 1993)?

From Fig. (a), the CIRCUMRADIUS of the base is  $a/\sqrt{2}$ . Now find  $h$  in terms of  $r$  and  $a$ . Fig. (b) shows a CROSS-SECTION cut by the plane through the pyramid's apex, one of the base's vertices, and the base center. This figure gives

$$b = \sqrt{\frac{1}{2}a^2 - r^2} \quad (4)$$

$$c = \sqrt{h^2 - r^2}, \quad (5)$$

so the SLANT HEIGHT is

$$s = \sqrt{h^2 + \frac{1}{2}a^2} = b + c = \sqrt{\frac{1}{2}a^2 - r^2} + \sqrt{h^2 - r^2}. \quad (6)$$

Solving for  $h$  gives

$$h = \frac{ra}{\sqrt{a^2 - 2r^2}}. \quad (7)$$

We know, however, that the HEMISPHERE must be tangent to the sides, so  $r = a/2$ , and

$$h = \frac{\frac{1}{2}a}{\sqrt{a^2 - \frac{1}{2}a^2}}a = \frac{\frac{1}{2}}{\sqrt{\frac{1}{2}}}a = \frac{1}{2}\sqrt{2}a. \quad (8)$$

Fig. (c) shows a CROSS-SECTION through the center, apex, and midpoints of opposite sides. The PYTHAGOREAN THEOREM once again gives

$$l = \sqrt{\frac{1}{4}a^2 + h^2} = \sqrt{\frac{1}{4}a^2 + \frac{1}{2}a^2} = \frac{1}{2}\sqrt{3}a. \quad (9)$$

We now need to find  $x$  and  $y$ .

$$\sqrt{\frac{1}{4}a^2 - x^2} + d = l. \quad (10)$$

But we know  $l$  and  $h$ , and  $d$  is given by

$$d = \sqrt{h^2 - x^2}, \quad (11)$$

so

$$\sqrt{\frac{1}{4}a^2 - x^2} + \sqrt{\frac{1}{2}a^2 - x^2} = \frac{1}{2}\sqrt{3}a. \quad (12)$$

Solving gives

$$x = \frac{1}{6}\sqrt{6}a, \quad (13)$$

so

$$y = \sqrt{r^2 - x^2} = \sqrt{\frac{1}{4} - \frac{1}{6}}a = \sqrt{\frac{3-2}{12}}a = \frac{a}{2\sqrt{3}}. \quad (14)$$

We can now find the AREA of the SPHERICAL CAP as

$$V_{\text{cap}} = \frac{1}{6}\pi H(3A^2 + H^2), \quad (15)$$

where

$$A \equiv y = \frac{a}{2\sqrt{3}} \quad (16)$$

$$H \equiv r - x = \frac{1}{2}a - \frac{a}{\sqrt{6}} = a\left(\frac{1}{2} - \frac{1}{\sqrt{6}}\right), \quad (17)$$

so

$$\begin{aligned} V_{\text{cap}} &= \frac{1}{6}\pi a^3 \left[ 3\left(\frac{1}{12}\right) + \left(\frac{1}{2} - \frac{1}{\sqrt{6}}\right)^2 \right] \left(\frac{1}{2} - \frac{1}{\sqrt{6}}\right) \\ &= \frac{1}{6}\pi a^3 \left[ \frac{1}{4} + \left(\frac{1}{4} + \frac{1}{6} - \frac{1}{\sqrt{6}}\right) \right] \left(\frac{1}{2} - \frac{1}{\sqrt{6}}\right) \\ &= \frac{1}{6}\pi a^3 \left( \frac{2}{3} - \frac{1}{\sqrt{6}} \right) \left(\frac{1}{2} - \frac{1}{\sqrt{6}}\right) \\ &= \frac{1}{6}\pi a^3 \left( \frac{1}{3} - \frac{1}{2\sqrt{6}} - \frac{2}{3\sqrt{6}} + \frac{1}{6} \right) \\ &= \frac{1}{6}\pi a^3 \left( \frac{1}{2} - \frac{7}{6\sqrt{6}} \right). \end{aligned} \quad (18)$$

Therefore, the volume within the pyramid is

$$\begin{aligned} V_{\text{inside}} &= \frac{2}{3}\pi r^3 - 4V_{\text{cap}} = \frac{2}{3}\pi \frac{1}{8}a^3 - \frac{2}{3}\pi a^3 \left( \frac{1}{2} - \frac{7}{6\sqrt{6}} \right) \\ &= \frac{2}{3}\pi a^3 \left( \frac{1}{8} - \frac{1}{2} + \frac{7}{6\sqrt{6}} \right) = \frac{2}{3}\pi a^3 \left( \frac{7}{6\sqrt{6}} - \frac{3}{8} \right) \\ &= \pi a^3 \left( \frac{7}{9\sqrt{6}} - \frac{1}{4} \right). \end{aligned} \quad (19)$$

This problem appeared in the Japanese scholastic aptitude test (Cipra 1993).

### Square Pyramidal Number

A FIGURATE NUMBER of the form

$$P_n = \frac{1}{6}n(n+1)(2n+1), \quad (1)$$

corresponding to a configuration of points which form a SQUARE PYRAMID, is called a square pyramidal number (or sometimes, simply a PYRAMIDAL NUMBER). The first few are 1, 5, 14, 30, 55, 91, 140, 204, ... (Sloane's A000330). They are sums of consecutive pairs of TETRAHEDRAL NUMBERS and satisfy

$$P_n = \frac{1}{3}(2n+1)T_n, \quad (2)$$

where  $T_n$  is the  $n$ th TRIANGULAR NUMBER.

The only numbers which are simultaneously SQUARE and pyramidal (the CANNONBALL PROBLEM) are  $P_1 = 1$  and  $P_{24} = 4900$ , corresponding to  $S_1 = 1$  and  $S_{70} = 4900$  (Dickson 1952, p. 25; Ball and Coxeter 1987, p. 59; Ogilvy 1988), as conjectured by Lucas (1875, 1876) and proved by Watson (1918). The proof is far from elementary, and is equivalent to solving the DIOPHANTINE EQUATION

$$y^2 = \frac{1}{6}x(x+1)(2x+1) \quad (3)$$

(Guy 1994, p. 147). However, an elementary proof has also been given by a number of authors.

Numbers which are simultaneously TRIANGULAR and square pyramidal satisfy the DIOPHANTINE EQUATION

$$3(2y+1)^2 = 8x^3 + 12x^2 + 4x + 3. \quad (4)$$

The only solutions are  $x = -1, 0, 1, 5, 6$ , and 85 (Guy 1994, p. 147). Beukers (1988) has studied the problem of finding numbers which are simultaneously TETRAHEDRAL and square pyramidal via INTEGER points on an ELLIPTIC CURVE. He finds that the only solution is the trivial  $Te_1 = P_1 = 1$ .

### Square Quadrants

The areas of the regions illustrated above can be found from the equations

$$A + 4B + 4C = 1 \quad (1)$$

$$A + 3B + 2C = \frac{1}{4}\pi. \quad (2)$$

Since we want to solve for three variables, we need a third equation. This can be taken as

$$A + 2B + C = 2E + D, \quad (3)$$

where

$$D = \frac{1}{4}\sqrt{3} \quad (4)$$

$$D + E = \frac{1}{6}\pi, \quad (5)$$

leading to

$$A + 2B + C = D + 2E = 2(D + E) - D = \frac{1}{3}\pi - \frac{1}{4}\sqrt{3}. \quad (6)$$

Combining the equations (1), (2), and (6) gives the matrix equation

$$\begin{bmatrix} 1 & 4 & 4 \\ 1 & 3 & 2 \\ 1 & 2 & 1 \end{bmatrix} \begin{bmatrix} A \\ B \\ C \end{bmatrix} = \begin{bmatrix} 1 \\ \frac{1}{4}\pi \\ \frac{1}{3}\pi - \frac{1}{4}\sqrt{3} \end{bmatrix}, \quad (7)$$

which can be inverted to yield

$$A = 1 - \sqrt{3} - \frac{1}{3}\pi \quad (8)$$

$$B = -1 + \frac{1}{2}\sqrt{3} + \frac{1}{12}\pi \quad (9)$$

$$C = 1 - \frac{1}{4}\sqrt{3} + \frac{1}{6}\pi. \quad (10)$$

### Square Root

A square root of  $x$  is a number  $r$  such that  $r^2 = x$ . This is written  $r = x^{1/2}$  ( $x$  to the  $1/2$  POWER) or  $r = \sqrt{x}$ . The square root function  $f(x) = \sqrt{x}$  is the INVERSE FUNCTION of  $f(x) = x^2$ . Square roots are also called RADICALS or SURDS. A general COMPLEX NUMBER  $z$  has *two* square roots. For example, for the real POSITIVE number  $x = 9$ , the two square roots are  $\sqrt{9} = \pm 3$ , since  $3^2 = (-3)^2 = 9$ . Similarly, for the real NEGATIVE number  $x = -9$ , the two square roots are  $\sqrt{-9} = \pm 3i$ , where  $i$  is the IMAGINARY NUMBER defined by  $i^2 = -1$ . In common usage, unless otherwise specified, "the" square root is generally taken to mean the POSITIVE square root.

The square root of 2 is the IRRATIONAL NUMBER  $\sqrt{2} \approx 1.41421356$  (Sloane's A002193), which has the simple periodic CONTINUED FRACTION 1, 2, 2, 2, 2, 2, .... The square root of 3 is the IRRATIONAL NUMBER  $\sqrt{3} \approx 1.73205081$  (Sloane's A002194), which has the simple periodic CONTINUED FRACTION 1, 1, 2, 1, 2, 1, 2, .... In general, the CONTINUED FRACTIONS of the square roots of all POSITIVE integers are periodic.

The square roots of a COMPLEX NUMBER are given by

$$\sqrt{x + iy} = \pm \sqrt{x^2 + y^2} \left\{ \cos \left[ \frac{1}{2} \tan^{-1} \left( \frac{y}{x} \right) \right] + i \sin \left[ \frac{1}{2} \tan^{-1} \left( \frac{y}{x} \right) \right] \right\}. \quad (1)$$

As can be seen in the above figure, the IMAGINARY PART of the complex square root function has a BRANCH CUT along the NEGATIVE real axis.

A NESTED RADICAL of the form  $\sqrt{a \pm b\sqrt{c}}$  can sometimes be simplified into a simple square root by equating

$$\sqrt{a \pm b\sqrt{c}} = \sqrt{d} \pm \sqrt{e}. \quad (2)$$

Squaring gives

$$a \pm b\sqrt{c} = d + e \pm 2\sqrt{de}, \quad (3)$$

so

$$a = d + e \quad (4)$$

$$b^2 c = 4de. \quad (5)$$

Solving for  $d$  and  $e$  gives

$$d, e = \frac{a \pm \sqrt{a^2 - b^2 c}}{2}. \quad (6)$$

A sequence of approximations  $a/b$  to  $\sqrt{n}$  can be derived by factoring

$$a^2 - nb^2 = \pm 1 \quad (7)$$

(where  $-1$  is possible only if  $-1$  is a QUADRATIC RESIDUE of  $n$ ). Then

$$(a + b\sqrt{n})(a - b\sqrt{n}) = \pm 1 \quad (8)$$

$$(a + b\sqrt{n})^k (a - b\sqrt{n})^k = (\pm 1)^k = \pm 1, \quad (9)$$

and

$$(1 + \sqrt{n})^1 = 1 + \sqrt{n} \quad (10)$$

$$(1 + \sqrt{n})^2 = (1 + n) + 2\sqrt{n} \quad (11)$$

$$(1 + \sqrt{n})(a + b\sqrt{n}) = (a + bn) + \sqrt{n}(a + b). \quad (12)$$

Therefore,  $a$  and  $b$  are given by the RECURRENCE RELATIONS

$$a_i = a_{i-1} + b_{i-1}n \quad (13)$$

$$b_i = a_{i-1} + b_{i-1} \quad (14)$$

with  $a_1 = b_1 = 1$ . The error obtained using this method is

$$\left| \frac{a}{b} - \sqrt{n} \right| = \frac{1}{b(a + b\sqrt{n})} < \frac{1}{2b^2}. \quad (15)$$

The first few approximants to  $\sqrt{n}$  are therefore given by

$$1, \frac{1}{2}(1 + n), \frac{1 + 3n}{3 + n}, \frac{1 + 6n + n^2}{4(n + 1)}, \frac{1 + 10n + 5n^2}{5 + 10n + n^2}, \dots \quad (16)$$

This ALGORITHM is sometimes known as the BHASKARA-BROUCKNER ALGORITHM. For the case  $n = 2$ , this gives the convergents to  $\sqrt{2}$  as 1, 3/2, 7/5, 17/12, 41/29, 99/70, ....

Another general technique for deriving this sequence, known as NEWTON'S ITERATION, is obtained by letting  $x = \sqrt{n}$ . Then  $x = n/x$ , so the SEQUENCE

$$x_k = \frac{1}{2} \left( x_{k-1} + \frac{n}{x_{k-1}} \right) \quad (17)$$

converges quadratically to the root. The first few approximants to  $\sqrt{n}$  are therefore given by

$$1, \frac{1}{2}(1 + n), \frac{1 + 6n + n^2}{4(n + 1)}, \frac{1 + 26n + 70n^2 + 28n^3 + n^4}{8(1 + n)(1 + 6n + n^2)}, \dots \quad (18)$$

For  $\sqrt{2}$ , this gives the convergents 1, 3/2, 17/12, 577/408, 665857/470832, ....

## Square Root Inequality

$$2\sqrt{n+1} - 2\sqrt{n} < \frac{1}{\sqrt{n}} < 2\sqrt{n} - 2\sqrt{n-1}.$$

## Square Root Method

The square root method is an algorithm which solves the MATRIX EQUATION

$$\mathbf{A}\mathbf{u} = \mathbf{g} \quad (1)$$

for  $\mathbf{u}$ , with  $\mathbf{A}$  a  $p \times p$  SYMMETRIC MATRIX and  $\mathbf{g}$  a given VECTOR. Convert  $\mathbf{A}$  to a TRIANGULAR MATRIX such that

$$\mathbf{T}^T \mathbf{T} = \mathbf{A}, \quad (2)$$

where  $\mathbf{T}^T$  is the MATRIX TRANSPOSE. Then

$$\mathbf{T}^T \mathbf{k} = \mathbf{g} \quad (3)$$

$$\mathbf{T}\mathbf{u} = \mathbf{k}, \quad (4)$$

so

$$\mathbf{T} = \begin{bmatrix} s_{11} & s_{12} & \cdots & \cdots \\ 0 & s_{22} & \cdots & \cdots \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & s_{pp} \end{bmatrix}, \quad (5)$$

giving the equations

$$\begin{aligned} s_{11}^2 &= a_{11} \\ s_{11}s_{12} &= a_{12} \\ s_{12}^2 + s_{22}^2 &= a_{22} \\ s_{1j}^2 + s_{2j}^2 + \cdots + s_{jj}^2 &= a_{jj} \\ s_{1j} + s_{2j}s_{2k} + \cdots + s_{jj}s_{jk} &= a_{jk}. \end{aligned} \quad (6)$$

These give

$$\begin{aligned} s_{11} &= \sqrt{a_{11}} \\ s_{12} &= \frac{a_{12}}{s_{11}} \\ s_{22} &= \sqrt{a_{22} - s_{12}^2} \\ s_{jj} &= \sqrt{a_{jj} - s_{1j}^2 - s_{2j}^2 - \cdots - s_{j-1,j}^2} \\ s_{jk} &= \frac{a_{jk} - s_{1j}s_{1k} - s_{2j}s_{2k} - \cdots - s_{j-1,j}s_{j-1,k}}{s_{jj}}, \end{aligned} \quad (7)$$

giving  $\mathbf{T}$  from  $\mathbf{A}$ . Now solve for  $\mathbf{k}$  in terms of the  $s_{ij}$ s and  $\mathbf{g}$ ,

$$\begin{aligned} s_{11}k_1 &= g_1 \\ s_{12}k_1 + s_{22}k_2 &= g_2 \\ s_{1j}k_1 + s_{2j}k_2 + \cdots + s_{jj}k_j &= g_j, \end{aligned} \quad (8)$$

which gives

$$\begin{aligned} k_1 &= \frac{g_1}{s_{11}} \\ k_2 &= \frac{g_2 - s_{12}k_1}{s_{22}} \\ k_j &= \frac{g_j - s_{1j}k_1 - s_{2j}k_2 - \cdots - s_{j-1,j}k_{j-1}}{s_{jj}}. \end{aligned} \quad (9)$$

Finally, find  $\mathbf{u}$  from the  $s_{ij}$ s and  $\mathbf{k}$ ,

$$\begin{aligned} s_{11}u_1 + s_{12}u_2 + \cdots + s_{1p}u_p &= k_1 \\ s_{22}u_2 + \cdots + s_{2p}u_p &= k_2 \\ s_{pp}u_p &= k_p, \end{aligned} \quad (10)$$

giving the desired solution,

$$\begin{aligned} u_p &= \frac{k_p}{s_{pp}} \\ u_{p-1} &= \frac{k_{p-1} - s_{p-1,p}u_p}{s_{p-1,p-1}} \\ u_j &= \frac{k_j - s_{j,j+1}u_{j+1} - s_{j,j+2}u_{j+2} - \cdots - s_{jp}u_p}{s_{jj}}. \end{aligned} \quad (11)$$

## Square Triangular Number

A number which is simultaneously SQUARE and TRIANGULAR. The first few are 1, 36, 1225, 41616, 1413721, 48024900, ... (Sloane's A001110), corresponding to  $T_1 = S_1$ ,  $T_8 = S_6$ ,  $T_{49} = S_{35}$ ,  $T_{288} = S_{204}$ ,  $T_{1681} = S_{1189}$ , ... (Pietenpol 1962), but there are an infinite number, as first shown by Euler in 1730 (Dickson 1952).

The general FORMULA for a square triangular number  $ST_n$  is  $b^2c^2$ , where  $b/c$  is the  $n$ th convergent to the CONTINUED FRACTION of  $\sqrt{2}$  (Ball and Coxeter 1987, p. 59; Conway and Guy 1996). The first few are

$$\frac{1}{1}, \frac{3}{2}, \frac{7}{5}, \frac{17}{12}, \frac{41}{29}, \frac{99}{70}, \frac{239}{169}, \dots \quad (1)$$

The NUMERATORS and DENOMINATORS give solutions to the PELL EQUATION

$$x^2 - 2y^2 = \pm 1, \quad (2)$$

but can also be obtained by doubling the previous FRACTION and adding to the FRACTION before that. The connection with the PELL EQUATION can be seen by letting  $N$  denote the  $N$ th TRIANGULAR NUMBER and  $M$  the  $M$ th SQUARE NUMBER, then

$$\frac{1}{2}N(N+1) = M^2. \quad (3)$$

Defining

$$x \equiv 2N + 1 \quad (4)$$

$$y \equiv 2M \quad (5)$$

then gives the equation

$$x^2 - 2y^2 = 1 \quad (6)$$

(Conway and Guy 1996). Numbers which are simultaneously TRIANGULAR and SQUARE PYRAMIDAL also satisfy the DIOPHANTINE EQUATION

$$3(2y+1)^2 = 8x^3 + 12x^2 + 4x + 3. \quad (7)$$

The only solutions are  $x = -1, 0, 1, 5, 6$ , and  $85$  (Guy 1994, p. 147).

A general FORMULA for square triangular numbers is

$$ST_n = \left[ \frac{(1 + \sqrt{2})^{2n} - (1 - \sqrt{2})^{2n}}{4\sqrt{2}} \right]^2 \quad (8)$$

$$= \frac{1}{32}[(17 + 12\sqrt{2})^n + (17 - 12\sqrt{2})^n - 2]. \quad (9)$$

The square triangular numbers also satisfy the RECURRENCE RELATION

$$ST_n = 34ST_{n-1} - ST_{n-2} + 2 \quad (10)$$

$$u_{n+2} = 6u_{n+1} - u_n, \quad (11)$$

with  $u_0 = 0, u_1 = 1$ , where  $ST_n \equiv u_n^2$ . A curious product formula for  $ST_n$  is given by

$$ST_n = 2^{2n-5} \prod_{k=1}^{2n} \left[ 3 + \cos\left(\frac{k\pi}{n}\right) \right]. \quad (12)$$

An amazing GENERATING FUNCTION is

$$f(x) = \frac{1+x}{(1-x)(1-34x+x^2)} = 1 + 36x + 1225x^2 + \dots \quad (13)$$

(Sloane and Plouffe 1995).

## Square Wave

The square wave is a periodic waveform consisting of instantaneous transitions between two levels which can be denoted  $\pm 1$ . The square wave is sometimes also called the RADEMACHER FUNCTION. Let the square wave have period  $2L$ . The square wave function is ODD, so the FOURIER SERIES has  $a_0 = a_n = 0$  and

$$\begin{aligned} b_n &= \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) dx \\ &= \frac{4}{n\pi} \sin^2\left(\frac{1}{2}n\pi\right) = \frac{4}{n\pi} \begin{cases} 0 & n \text{ even} \\ 1 & n \text{ odd.} \end{cases} \end{aligned}$$

The FOURIER SERIES for the square wave is therefore

$$f(x) = \frac{4}{\pi} \sum_{n=1,3,5,\dots}^{\infty} \frac{1}{n} \sin\left(\frac{n\pi x}{L}\right).$$

## Squared

A number to the POWER 2 is said to be squared, so that  $x^2$  is called "x squared."

see also CUBED, SQUARE ROOT

**Squared Square**

see PERFECT SQUARE DISSECTION

**Squarefree**

A number is said to be squarefree (or sometimes QUADRATFREI; Shanks 1993) if its PRIME decomposition contains no repeated factors. All PRIMES are therefore trivially squarefree. The squarefree numbers are 1, 2, 3, 5, 6, 7, 10, 11, 13, 14, 15, ... (Sloane's A005117). The SQUAREFUL numbers (i.e., those that contain at least one square) are 4, 8, 9, 12, 16, 18, 20, 24, 25, ... (Sloane's A013929).

The asymptotic number  $Q(n)$  of squarefree numbers  $\leq n$  is given by

$$Q(n) = \frac{6n}{\pi^2} + \mathcal{O}(\sqrt{n}) \quad (1)$$

(Hardy and Wright 1979, pp. 269–270).  $Q(n)$  for  $n = 10, 100, 1000, \dots$  are 7, 61, 608, 6083, 60794, 607926, ..., while the asymptotic density is  $1/\zeta(2) = 6/\pi^2 \approx 0.607927$ , where  $\zeta(n)$  is the RIEMANN ZETA FUNCTION.

The MÖBIUS FUNCTION is given by

$$\mu(n) \equiv \begin{cases} 0 & \text{if } n \text{ has one or more repeated prime factors} \\ 1 & \text{if } n = 1 \\ (-1)^k & \text{if } n \text{ is product of } k \text{ distinct primes,} \end{cases} \quad (2)$$

so  $\mu(n) \neq 0$  indicates that  $n$  is squarefree. The asymptotic formula for  $Q(x)$  is equivalent to the formula

$$\sum_{n=1}^x |\mu(n)| = \frac{6x}{\pi^2} + \mathcal{O}(\sqrt{x}) \quad (3)$$

(Hardy and Wright 1979, p. 270)

There is no known polynomial-time algorithm for recognizing squarefree INTEGERS or for computing the squarefree part of an INTEGER. In fact, this problem may be no easier than the general problem of integer factorization (obviously, if an integer  $n$  can be factored completely,  $n$  is squarefree IFF it contains no duplicated factors). This problem is an important unsolved problem in NUMBER THEORY because computing the

RING of integers of an algebraic number field is reducible to computing the squarefree part of an INTEGER (Lenstra 1992, Pohst and Zassenhaus 1997). The *Mathematica*® (Wolfram Research, Champaign, IL) function `NumberTheory`NumberTheoryFunctions`SquareFreeQ[n]` determines whether a number is squarefree.

The largest known SQUAREFUL FIBONACCI NUMBER is  $F_{336}$ , and no SQUAREFUL FIBONACCI NUMBERS  $F_p$  are known with  $p$  PRIME. All numbers less than  $2.5 \times 10^{15}$  in SYLVESTER'S SEQUENCE are squarefree, and no SQUAREFUL numbers in this sequence are known (Vardi 1991). Every CARMICHAEL NUMBER is squarefree. The BINOMIAL COEFFICIENTS  $\binom{2n-1}{n}$  are squarefree only for  $n = 2, 3, 4, 6, 9, 10, 12, 36, \dots$ , with no others less than  $n = 1500$ . The CENTRAL BINOMIAL COEFFICIENTS are SQUAREFREE only for  $n = 1, 2, 3, 4, 5, 7, 8, 11, 17, 19, 23, 71, \dots$  (Sloane's A046098), with no others less than 1500.

**Squareful**

A number is squareful, also called NONSQUAREFREE, if it contains at least one SQUARE in its prime factorization. Such a number is also called SQUAREFUL. The first few are 4, 8, 9, 12, 16, 18, 20, 24, 25, ... (Sloane's A013929). The greatest multiple prime factors for the squareful integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 3, ... (Sloane's A046028). The least multiple prime factors for squareful integers are 2, 2, 3, 2, 2, 3, 2, 2, 5, 3, 2, 2, 2, ... (Sloane's A046027).

## Squaring

Squaring is the GEOMETRIC CONSTRUCTION, using only COMPASS and STRAIGHTEDGE, of a SQUARE which has the same area as a given geometric figure. Squaring is also called QUADRATURE. An object which can be constructed by squaring is called SQUARABLE.

see also CIRCLE SQUARING, COMPASS, CONSTRUCTIBLE NUMBER, GEOMETRIC CONSTRUCTION, RECTANGLE SQUARING, STRAIGHTEDGE, TRIANGLE SQUARING

## Squeezing Theorem

Let there be two functions  $f_-(x)$  and  $f_+(x)$  such that  $f(x)$  is "squeezed" between the two,

$$f_-(x) \leq f(x) \leq f_+(x).$$

If

$$r = \lim_{x \rightarrow a} f_-(x) = \lim_{x \rightarrow a} f_+(x),$$

then  $\lim_{x \rightarrow a} f(x) = r$ . In the above diagram the functions  $f_-(x) = -x^2$  and  $f_+(x) = x^2$  "squeeze"  $x^2 \sin(cx)$  at 0, so  $\lim_{x \rightarrow 0} x^2 \sin(cx) = 0$ . The squeezing theorem is also called the SANDWICH THEOREM.

## SSS Theorem

Specifying three sides uniquely determines a TRIANGLE whose AREA is given by HERON'S FORMULA,

$$A = \sqrt{s(s-a)(s-b)(s-c)}, \quad (1)$$

where

$$s \equiv \frac{1}{2}(a+b+c) \quad (2)$$

is the SEMIPERIMETER of the TRIANGLE. Let  $R$  be the CIRCUMRADIUS, then

$$A = \frac{abc}{4R}. \quad (3)$$

Using the LAW OF COSINES

$$a^2 = b^2 + c^2 - 2bc \cos A \quad (4)$$

$$b^2 = a^2 + c^2 - 2ac \cos B \quad (5)$$

$$c^2 = a^2 + b^2 - 2ab \cos C \quad (6)$$

gives the three ANGLES as

$$A = \cos^{-1} \left( \frac{b^2 + c^2 - a^2}{2bc} \right) \quad (7)$$

$$B = \cos^{-1} \left( \frac{b^2 + c^2 - b^2}{2ac} \right) \quad (8)$$

$$C = \cos^{-1} \left( \frac{a^2 + b^2 - c^2}{2ab} \right). \quad (9)$$

see also AAA THEOREM, AAS THEOREM, ASA THEOREM, ASS THEOREM, HERON'S FORMULA, SAS THEOREM, SEMIPERIMETER, TRIANGLE

## Stability

The robustness of a given outcome to small changes in initial conditions or small random fluctuations. CHAOS is an example of a process which is not stable.

see also STABILITY MATRIX

## Stability Matrix

Given a system of two ordinary differential equations

$$\dot{x} = f(x, y) \quad (1)$$

$$\dot{y} = g(x, y), \quad (2)$$

let  $x_0$  and  $y_0$  denote FIXED POINTS with  $\dot{x} = \dot{y} = 0$ , so

$$f(x_0, y_0) = 0 \quad (3)$$

$$g(x_0, y_0) = 0. \quad (4)$$

Then expand about  $(x_0, y_0)$  so

$$\begin{aligned} \delta \dot{x} &= f_x(x_0, y_0)\delta x + f_y(x_0, y_0)\delta y \\ &\quad + f_{xy}(x_0, y_0)\delta x \delta y + \dots \end{aligned} \quad (5)$$

$$\begin{aligned} \delta \dot{y} &= g_x(x_0, y_0)\delta x + g_y(x_0, y_0)\delta y \\ &\quad + g_{xy}(x_0, y_0)\delta x \delta y + \dots \end{aligned} \quad (6)$$

To first-order, this gives

$$\frac{d}{dt} \begin{bmatrix} \delta x \\ \delta y \end{bmatrix} = \begin{bmatrix} f_x(x_0, y_0) & f_y(x_0, y_0) \\ g_x(x_0, y_0) & g_y(x_0, y_0) \end{bmatrix} \begin{bmatrix} \delta x \\ \delta y \end{bmatrix}, \quad (7)$$

where the  $2 \times 2$  MATRIX, or its generalization to higher dimension, is called the stability matrix. Analysis of the EIGENVALUES (and EIGENVECTORS) of the stability matrix characterizes the type of FIXED POINT.

### Stable Type

A POLYNOMIAL equation whose ROOTS all have NEGATIVE REAL PARTS. For a REAL QUADRATIC EQUATION

$$z^2 + Bz + C = 0,$$

the stability conditions are  $B, C > 0$ . For a REAL CUBIC EQUATION

$$z^3 + Az^2 + Bz + C = 0,$$

the stability conditions are  $A, B, C > 0$  and  $AB > C$ .

### Stack

A DATA STRUCTURE which is a special kind of LIST in which elements may be added to or removed from the top only. These actions are called a PUSH or a POP, respectively. Actions may be taken by popping one or more values, operating on them, and then pushing the result back onto the stack.

Stacks are used as the basis for computer languages such as FORTH, PostScript® (Adobe Systems), and the RPN language used in Hewlett-Packard® programmable calculators.

see also LIST, POP, PUSH, QUEUE

### Stäckel Determinant

A DETERMINANT used to determine in which coordinate systems the HELMHOLTZ DIFFERENTIAL EQUATION is separable (Morse and Feshbach 1953). A determinant

$$S = |\Phi_{mn}| = \begin{vmatrix} \Phi_{11} & \Phi_{12} & \Phi_{13} \\ \Phi_{21} & \Phi_{22} & \Phi_{23} \\ \Phi_{31} & \Phi_{32} & \Phi_{33} \end{vmatrix} \quad (1)$$

in which  $\Phi_{ni}$  are functions of  $u_i$  alone is called a Stäckel determinant. A coordinate system is separable if it obeys the ROBERTSON CONDITION, namely that the SCALE FACTORS  $h_i$  in the LAPLACIAN

$$\nabla^2 = \sum_{i=1}^3 \frac{1}{h_1 h_2 h_3} \frac{\partial}{\partial u_i} \left( \frac{h_1 h_2 h_3}{h_i^2} \frac{\partial}{\partial u_i} \right) \quad (2)$$

can be rewritten in terms of functions  $f_i(u_i)$  defined by

$$\begin{aligned} \frac{1}{h_1 h_2 h_3} \frac{\partial}{\partial u_i} \left( \frac{h_1 h_2 h_3}{h_i^2} \frac{\partial}{\partial u_i} \right) \\ = \frac{g(u_{i+1}, u_{i+2})}{h_1 h_2 h_3} \frac{\partial}{\partial u_i} \left[ f_i(u_i) \frac{\partial}{\partial u_i} \right] \\ = \frac{1}{h_i^2 f_i} \frac{\partial}{\partial u_i} \left( f_i \frac{\partial}{\partial u_i} \right) \end{aligned} \quad (3)$$

such that  $S$  can be written

$$S = \frac{h_1 h_2 h_3}{f_1(u_1) f_2(u_2) f_3(u_3)}. \quad (4)$$

When this is true, the separated equations are of the form

$$\frac{1}{f_n} \frac{\partial}{\partial u_n} \left( f_n \frac{\partial X_n}{\partial u_n} \right) + (k_1^2 \Phi_{n1} + k_2^2 \Phi_{n2} + k_3^2 \Phi_{n3}) X_n = 0 \quad (5)$$

The  $\Phi_{ij}$ s obey the minor equations

$$M_1 = \Phi_{22} \Phi_{33} - \Phi_{23} \Phi_{32} = \frac{S}{h_1^2} \quad (6)$$

$$M_2 = \Phi_{13} \Phi_{31} - \Phi_{12} \Phi_{33} = \frac{S}{h_2^2} \quad (7)$$

$$M_3 = \Phi_{12} \Phi_{23} - \Phi_{13} \Phi_{22} = \frac{S}{h_3^2}, \quad (8)$$

which are equivalent to

$$M_1 \Phi_{11} + M_2 \Phi_{21} + M_3 \Phi_{31} = S \quad (9)$$

$$M_1 \Phi_{12} + M_2 \Phi_{22} + M_3 \Phi_{32} = 0 \quad (10)$$

$$M_1 \Phi_{13} + M_2 \Phi_{23} + M_3 \Phi_{33} = 0. \quad (11)$$

This gives a total of four equations in nine unknowns. Morse and Feshbach (1953, pp. 655–666) give not only the Stäckel determinants for common coordinate systems, but also the elements of the determinant (although it is not clear how these are derived).

### Stamp Folding

The number of ways of folding a strip of stamps has several possible variants. Considering only positions of the hinges for unlabeled stamps without regard to orientation of the stamps, the number of foldings is denoted  $U(n)$ . If the stamps are labelled and orientation is taken into account, the number of foldings is denoted  $N(n)$ . Finally, the number of symmetric foldings is denoted  $S(n)$ . The following table summarizes these values for the first  $n$ .

$n$	$S(n)$	$U(n)$	$N(n)$
1	1	1	1
2	1	1	1
3	2	2	6
4	4	5	16
5	6	14	50
6	8	39	144
7	18	120	462
8	20	358	1392
9	56	1176	4536
10		3572	

see also MAP FOLDING

### Standard Deviation

The standard deviation is defined as the SQUARE ROOT of the VARIANCE,

$$\sigma = \sqrt{\langle x^2 \rangle - \langle x \rangle^2} = \sqrt{\mu'_2 - \mu^2}, \quad (1)$$

where  $\mu = \langle x \rangle$  is the MEAN and  $\mu'_2 = \langle x^2 \rangle$  is the second MOMENT about 0. The variance  $\sigma^2$  is equal to the second MOMENT about the MEAN,

$$\sigma^2 = \mu_2. \quad (2)$$

The square root of the SAMPLE VARIANCE is the "sample" standard deviation,

$$s_N = \sqrt{\frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^2}. \quad (3)$$

It is a BIASED ESTIMATOR of the population standard deviation. As unbiased ESTIMATOR is given by

$$s_{N-1} = \sqrt{\frac{1}{N-1} \sum_{i=1}^N (x_i - \bar{x})^2}. \quad (4)$$

Physical scientists often use the term ROOT-MEAN-SQUARE as a synonym for standard deviation when they refer to the SQUARE ROOT of the mean squared deviation of a signal from a given baseline or fit.

see also MEAN, MOMENT, ROOT-MEAN-SQUARE, SAMPLE VARIANCE, STANDARD ERROR, VARIANCE

### Standard Error

The square root of the ESTIMATED VARIANCE of a quantity. The standard error is also sometimes used to mean

$$\text{var}(\bar{x}) = \sum_{i=1}^n \left(\frac{1}{n}\right)^2 \sigma_i^2 = \sum_{i=1}^n \left(\frac{1}{n}\right)^2 \sigma^2 = \frac{\sigma^2}{n}.$$

see also STANDARD DEVIATION

### Standard Map

A 2-D MAP, also called the TAYLOR-GREENE-CHIRIKOV MAP in some of the older literature.

$$I_{n+1} = I_n + K \sin \theta_n \quad (1)$$

$$\theta_{n+1} = \theta_n + I_{n+1} = I_n + \theta_n + K \sin \theta_n, \quad (2)$$

where  $I$  and  $\theta$  are computed mod  $2\pi$  and  $K$  is a POSITIVE constant. An analytic estimate of the width of the CHAOTIC zone (Chirikov 1979) finds

$$\delta I = B e^{-AK^{-1/2}}. \quad (3)$$

Numerical experiments give  $A \approx 5.26$  and  $B \approx 240$ . The value of  $K$  at which global CHAOS occurs has been

bounded by various authors. GREENE'S METHOD is the most accurate method so far devised.

Author	Bound	Fraction	Decimal
Hermann	$>$	$\frac{1}{34}$	0.029411764
Italians	$>$	—	0.65
Greene	$\approx$	—	0.971635406
MacKay and Pearson	$<$	$\frac{63}{64}$	0.984375000
Mather	$<$	$\frac{4}{3}$	1.333333333

FIXED POINTS are found by requiring that

$$I_{n+1} = I_n \quad (4)$$

$$\theta_{n+1} = \theta_n. \quad (5)$$

The first gives  $K \sin \theta_n = 0$ , so  $\sin \theta_n = 0$  and

$$\theta_n = 0, \pi. \quad (6)$$

The second requirement gives

$$I_n + K \sin \theta_n = I_n = 0. \quad (7)$$

The FIXED POINTS are therefore  $(I, \theta) = (0, 0)$  and  $(0, \pi)$ . In order to perform a LINEAR STABILITY analysis, take differentials of the variables

$$dI_{n+1} = dI_n + K \cos \theta_n d\theta_n \quad (8)$$

$$d\theta_{n+1} = dI_n + (1 + K \cos \theta_n) d\theta_n. \quad (9)$$

In MATRIX form,

$$\begin{bmatrix} \delta I_{n+1} \\ \delta \theta_{n+1} \end{bmatrix} = \begin{bmatrix} 1 & K \cos \theta_n \\ 1 & 1 + K \cos \theta_n \end{bmatrix} \begin{bmatrix} \delta I_n \\ \delta \theta_n \end{bmatrix}. \quad (10)$$

The EIGENVALUES are found by solving the CHARACTERISTIC EQUATION

$$\begin{vmatrix} 1 - \lambda & K \cos \theta_n \\ 1 & 1 + K \cos \theta_n - \lambda \end{vmatrix} = 0, \quad (11)$$

so

$$\lambda^2 - \lambda(K \cos \theta_n + 2) + 1 = 0 \quad (12)$$

$$\lambda_{\pm} = \frac{1}{2} [K \cos \theta_n + 2 \pm \sqrt{(K \cos \theta_n + 2)^2 - 4}]. \quad (13)$$

For the FIXED POINT  $(0, \pi)$ ,

$$\begin{aligned} \lambda_{\pm}^{(0, \pi)} &= \frac{1}{2} [2 - K \pm \sqrt{(2 - K)^2 - 4}] \\ &= \frac{1}{2} (2 - K \pm \sqrt{K^2 - 4K}). \end{aligned} \quad (14)$$

The FIXED POINT will be stable if  $|\Re(\lambda^{(0, \pi)})| < 2$ . Here, that means

$$\frac{1}{2} |2 - K| < 1 \quad (15)$$

$$|2 - K| < 2 \quad (16)$$

$$-2 < 2 - K < 2 \quad (17)$$

$$-4 < -K < 0 \quad (18)$$

so  $K \in [0, 4)$ . For the FIXED POINT  $(0, 0)$ , the EIGENVALUES are

$$\begin{aligned}\lambda_{\pm}^{(0,0)} &= \frac{1}{2}[2 + K \pm \sqrt{(K+2)^2 - 4}] \\ &= \frac{1}{2}(2 + K \pm \sqrt{K^2 + 4K}).\end{aligned}\quad (19)$$

If the map is unstable for the larger EIGENVALUE, it is unstable. Therefore, examine  $\lambda_+^{(0,0)}$ . We have

$$\frac{1}{2} \left| 2 + K + \sqrt{K^2 + 4K} \right| < 1, \quad (20)$$

so

$$-2 < 2 + K + \sqrt{K^2 + 4K} < 2 \quad (21)$$

$$-4 - K < \sqrt{K^2 + 4K} < -K. \quad (22)$$

But  $K > 0$ , so the second part of the inequality cannot be true. Therefore, the map is unstable at the FIXED POINT  $(0, 0)$ .

$$y = (c + a \cos v) \sin u \quad (2)$$

$$z = a \sin v. \quad (3)$$

The three different classes of standard tori arise from the three possible relative sizes of  $a$  and  $c$ .  $c > a$  corresponds to the RING TORUS shown above,  $c = a$  corresponds to a HORN TORUS which touches itself at the point  $(0, 0, 0)$ , and  $c < a$  corresponds to a self-intersecting SPINDLE TORUS (Pinkall 1986). If no specification is made, "torus" is taken to mean RING TORUS.

The standard tori and their inversions are CYCLIDES.

**Star**

In formal geometry, a star is a set of  $2n$  VECTORS  $\pm \mathbf{a}_1, \dots, \pm \mathbf{a}_n$  which form a fixed center in EUCLIDEAN 3-SPACE. In common usage, a star is a STAR POLYGON (i.e., regular convex polygon) such as the PENTAGRAM or HEXAGRAM

see also CROSS, EUTACTIC STAR, STAR OF GOLIATH, STAR POLYGON

**Star of David**

see HEXAGRAM

**Star Figure**

A STAR POLYGON-like figure  $\left\{\frac{p}{q}\right\}$  for which  $p$  and  $q$  are not RELATIVELY PRIME.

see also STAR POLYGON

**Star (Fixed Point)**

A FIXED POINT which has one zero EIGENVECTOR.

see STABLE STAR, UNSTABLE STAR

**Star Fractal**

A FRACTAL composed of repeated copies of a PENTAGRAM or other polygon.

The above figure shows a generalization to different off-sets from the center.

**References**

- Lauwerier, H. *Fractals: Endlessly Repeated Geometric Figures*. Princeton, NJ: Princeton University Press, pp. 72–77, 1991.

**Star of Goliath**

see NONAGRAM

**Star Graph**

The  $k$ -star graph is a TREE on  $k + 1$  nodes with one node having valency  $k$  and the others having valency 1. Star graphs  $S_n$  are always GRACEFUL.

**Star of Lakshmi**

The STAR FIGURE  $\{8/2\}$ , which is used by Hindus to symbolize *Ashtalakshmi*, the eight forms of wealth. This symbol appears prominently in the Lugash national museum portrayed in the fictional film *Return of the Pink Panther*.

see also DISSECTION, HEXAGRAM, PENTAGRAM, STAR FIGURE, STAR POLYGON

**References**

- Savio, D. Y. and Suryanarayan, E. R. "Chebyshev Polynomials and Regular Polygons." *Amer. Math. Monthly* **100**, 657–661, 1993.

**Star Number**

The number of cells in a generalized Chinese checkers board (or "centered" HEXAGRAM).

$$S_n = 6n(n+1) + 1 = S_{n-1} + 12(n-1). \quad (1)$$

The first few are 1, 13, 37, 73, 121, ... (Sloane's A003154). Every star number has DIGITAL ROOT 1 or 4, and the final digits must be one of: 01, 21, 41, 61, 81, 13, 33, 53, 73, 93, or 37.

The first TRIANGULAR star numbers are 1, 253, 49141, 9533161, ... (Sloane's A006060), and can be computed using

$$\begin{aligned} TS_n &= \frac{3[(7+4\sqrt{3})^{2n-1} + (7-4\sqrt{3})^{2n-1}] - 10}{32} \\ &= 194TS_{n-1} + 60 - TS_{n-2}. \end{aligned} \quad (2)$$

The first few SQUARE star numbers are 1, 121, 11881, 1164241, 114083761, ... (Sloane's A006061). SQUARE star numbers are obtained by solving the DIOPHANTINE EQUATION

$$2x^2 + 1 = 3y^2 \quad (3)$$

and can be computed using

$$SS_n = \frac{[(5 + 2\sqrt{6})^n(\sqrt{6} - 2) - (5 - 2\sqrt{6})^n(\sqrt{6} + 2)]^2}{4}. \quad (4)$$

### Star Polygon

A star polygon  $\{p/q\}$ , with  $p, q$  POSITIVE INTEGERS, is a figure formed by connecting with straight lines every  $q$ th point out of  $p$  regularly spaced points lying on a CIRCUMFERENCE. The number  $q$  is called the DENSITY of the star polygon. Without loss of generality, take  $q < p/2$ .

The usual definition (Coxeter 1969) requires  $p$  and  $q$  to be RELATIVELY PRIME. However, the star polygon can also be generalized to the STAR FIGURE (or "improper" star polygon) when  $p$  and  $q$  share a common divisor (Savio and Suryanarayan 1993). For such a figure, if all points are not connected after the first pass, i.e., if  $(p, q) \neq 1$ , then start with the first unconnected point and repeat the procedure. Repeat until all points are connected. For  $(p, q) \neq 1$ , the  $\{p/q\}$  symbol can be factored as

$$\left\{ \frac{p}{q} \right\} = n \left\{ \frac{p'}{q'} \right\}, \quad (1)$$

where

$$p' \equiv \frac{p}{n} \quad (2)$$

$$q' \equiv \frac{q}{n}, \quad (3)$$

to give  $n \{p'/q'\}$  figures, each rotated by  $2\pi/p$  radians, or  $360^\circ/p$ .

If  $q = 1$ , a REGULAR POLYGON  $\{p\}$  is obtained. Special cases of  $\{p/q\}$  include  $\{5/2\}$  (the PENTAGRAM),  $\{6/2\}$  (the HEXAGRAM, or STAR OF DAVID),  $\{8/2\}$  (the STAR OF LAKSHMI),  $\{8/3\}$  (the OCTAGRAM),  $\{10/3\}$  (the DECAGRAM), and  $\{12/5\}$  (the DODECAGRAM).

The star polygons were first systematically studied by Thomas Bradwardine.

### State Space

The measurable space  $(S', S')$  into which a RANDOM VARIABLE from a PROBABILITY SPACE is a measurable function.

see also PROBABILITY SPACE, RANDOM VARIABLE

### Stationary Point

A point  $x_0$  at which the DERIVATIVE of a FUNCTION  $f(x)$  vanishes,

$$f'(x_0) = 0.$$

A stationary point may be a MINIMUM, MAXIMUM, or INFLECTION POINT.

see also CRITICAL POINT, DERIVATIVE, EXTREMUM, FIRST DERIVATIVE TEST, INFLECTION POINT, MAXIMUM, MINIMUM, SECOND DERIVATIVE TEST

## Stationary Tangent

see INFLECTION POINT

## Stationary Value

The value at a STATIONARY POINT.

## Statistic

A function of one or more random variables.

see also ANDERSON-DARLING STATISTIC, KUIPER STATISTIC, VARIATE

## Statistical Test

A test used to determine the statistical SIGNIFICANCE of an observation. Two main types of error can occur:

1. A TYPE I ERROR occurs when a false negative result is obtained in terms of the NULL HYPOTHESIS by obtaining a *false positive measurement*.
2. A TYPE II ERROR occurs when a false positive result is obtained in terms of the NULL HYPOTHESIS by obtaining a *false negative measurement*.

The probability that a statistical test will be positive for a true statistic is sometimes called the test's SENSITIVITY, and the probability that a test will be negative for a negative statistic is sometimes called the SPECIFICITY. The following table summarizes the names given to the various combinations of the actual state of affairs and observed test results.

result	name
true positive result	sensitivity
false negative result	1 – sensitivity
true negative result	specificity
false positive result	1 – specificity

Multiple-comparison corrections to statistical tests are used when several statistical tests are being performed simultaneously. For example, let's suppose you were measuring leg length in eight different lizard species and wanted to see whether the MEANS of any pair were different. Now, there are  $8!/2!6! = 28$  pairwise comparisons possible, so even if all of the *population* means are equal, it's quite likely that at least one pair of sample means would differ significantly at the 5% level. An ALPHA VALUE of 0.05 is therefore appropriate for each individual comparison, but not for the set of *all* comparisons.

In order to avoid a lot of spurious positives, the ALPHA VALUE therefore needs to be lowered to account for the

number of comparisons being performed. This is a correction for multiple comparisons. There are *many* different ways to do this. The simplest, and the most conservative, is the BONFERRONI CORRECTION. In practice, more people are more willing to accept false positives (false rejection of NULL HYPOTHESIS) than false negatives (false acceptance of NULL HYPOTHESIS), so less conservative comparisons are usually used.

## Staudt-Clausen Theorem

see VON STAUDT-CLAUSEN THEOREM

## Steenrod Algebra

The Steenrod algebra has to do with the COHOMOLOGY operations in singular COHOMOLOGY with INTEGER mod 2 COEFFICIENTS. For every  $n \in \mathbb{Z}$  and  $i \in \{0, 1, 2, 3, \dots\}$  there are natural transformations of FUNCTORS

$$Sq^i : H^n(\bullet; \mathbb{Z}_2) \rightarrow H^{n+i}(\bullet; \mathbb{Z}_2)$$

satisfying:

1.  $Sq^i = 0$  for  $i > n$ .
2.  $Sq^n(x) = x \smile x$  for all  $x \in H^n(X, A; \mathbb{Z}_2)$  and all pairs  $(X, A)$ .
3.  $Sq^0 = id_{H^n(\bullet; \mathbb{Z}_2)}$ .
4. The  $Sq^i$  maps commute with the coboundary maps in the long exact sequence of a pair. In other words,

$$Sq^i : H^*(\bullet; \mathbb{Z}_2) \rightarrow H^{*+i}(\bullet; \mathbb{Z}_2)$$

is a degree  $i$  transformation of cohomology theories.

5. (CARTAN RELATION)

$$Sq^i(x \smile y) = \sum_{j+k=i} Sq^j(x) \smile Sq^k(y).$$

6. (ADEM RELATIONS) For  $i < 2j$ ,

$$Sq^i \circ Sq^j(x) = \sum_{k=0}^{\lfloor i \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} \circ Sq^k(x).$$

7.  $Sq^i \circ \Sigma = \Sigma \circ Sq^i$  where  $\Sigma$  is the cohomology suspension isomorphism.

The existence of these cohomology operations endows the cohomology ring with the structure of a MODULE over the Steenrod algebra  $\mathcal{A}$ , defined to be  $T(F_{\mathbb{Z}_2}\{Sq^i : i \in \{0, 1, 2, 3, \dots\}\})/R$ , where  $F_{\mathbb{Z}_2}(\bullet)$  is the free module functor that takes any set and sends it to the free  $\mathbb{Z}_2$  module over that set. We think of  $F_{\mathbb{Z}_2}\{Sq^i : i \in \{0, 1, 2, \dots\}\}$  as being a graded  $\mathbb{Z}_2$  module, where the  $i$ -th gradation is given by  $\mathbb{Z}_2 \cdot Sq^i$ . This makes the tensor algebra  $T(F_{\mathbb{Z}_2}\{Sq^i : i \in \{0, 1, 2, 3, \dots\}\})$  into a GRADED ALGEBRA over  $\mathbb{Z}_2$ .  $R$  is the IDEAL generated by the elements  $Sq^i Sq^j + \sum_{k=0}^{\lfloor i \rfloor} \binom{j-k-1}{i-2k} Sq^{i+j-k} Sq^k$  and

$1 + Sq^0$  for  $0 < i < 2j$ . This makes  $\mathcal{A}$  into a graded  $\mathbb{Z}_2$  algebra.

By the definition of the Steenrod algebra, for any SPACE  $(X, \mathcal{A})$ ,  $H^*(X, \mathcal{A}; \mathbb{Z}_2)$  is a MODULE over the Steenrod algebra  $\mathcal{A}$ , with multiplication induced by  $Sq^i \cdot x \equiv Sq^i(x)$ . With the above definitions, cohomology with COEFFICIENTS in the RING  $\mathbb{Z}_2$ ,  $H^*(\bullet; \mathbb{Z}_2)$  is a FUNCTOR from the category of pairs of TOPOLOGICAL SPACES to graded modules over  $\mathcal{A}$ .

### Steenrod-Eilenberg Axioms

see EILENBERG-STEENROD AXIOMS

### Steenrod's Realization Problem

When can homology classes be realized as the image of fundamental classes of MANIFOLDS? The answer is known, and singular BORDISM GROUPS provide insight into this problem.

see also BORDISM GROUP, MANIFOLD

### Steepest Descent Method

An ALGORITHM for calculating the GRADIENT  $\nabla f(\mathbf{P})$  of a function at an  $n$ -D point  $\mathbf{P}$ . The steepest descent method starts at a point  $\mathbf{P}_0$  and, as many times as needed, moves from  $\mathbf{P}_i$  to  $\mathbf{P}_{i+1}$  by minimizing along the line extending from  $\mathbf{P}_i$  in the direction of  $-\nabla f(\mathbf{P}_i)$ , the local downhill gradient. This method has the severe drawback of requiring a great many iterations for functions which have long, narrow valley structures. In such cases, a CONJUGATE GRADIENT METHOD is preferable.

see also CONJUGATE GRADIENT METHOD, GRADIENT

## Steiner Chain

Given two nonconcentric CIRCLES with one interior to the other, if small TANGENT CIRCLES can be inscribed around the region between the two CIRCLES such that the final CIRCLE is TANGENT to the first, the CIRCLES form a Steiner chain.

The simplest way to construct a Steiner chain is to perform an INVERSION on a symmetrical arrangement on  $n$  circles packed between a central circle of radius  $b$  and an outer concentric circle of radius  $a$ . In this arrangement,

$$\sin\left(\frac{\pi}{n}\right) = \frac{a-b}{a+b}, \quad (1)$$

so the ratio of the radii for the small and large circles is

$$\frac{b}{a} = \frac{1 - \sin\left(\frac{\pi}{n}\right)}{1 + \sin\left(\frac{\pi}{n}\right)}. \quad (2)$$

To transform the symmetrical arrangement into a Steiner chain, find an INVERSION CENTER which transforms two centers initially offset by a fixed distance  $c$  to the same point. This can be done by equating

$$\frac{k^2 x}{x^2 - a^2} = \frac{k^2(x-c)}{(x-c)^2 - b^2}, \quad (3)$$

giving the offset of the inversion center from the large circle's center as

$$x = \frac{a^2 - b^2 + c^2 \pm \sqrt{(a^2 - b^2 + c^2)^2 - 4a^2c^2}}{2c}. \quad (4)$$

Plugging in a fixed value of  $a$  fixes  $b$ , which therefore determines  $x$  for a given  $c$ . Equivalently, a Steiner chain results whenever the INVERSIVE DISTANCE between the two original circles is given by

$$\delta = 2 \ln \left[ \sec\left(\frac{\pi}{n}\right) + \tan\left(\frac{\pi}{n}\right) \right] \quad (5)$$

$$= 2 \ln \left[ \tan\left(\frac{\pi}{4} + \frac{\pi}{2n}\right) \right] \quad (6)$$

(Coxeter and Greitzer 1967). The centers of the circles in a Steiner chain lie on an ELLIPSE (Ogilvy 1990, p. 57).

STEINER'S PORISM states that if a Steiner chain is formed from one starting circle, then a Steiner chain is also formed from any other starting circle.

## Steiner Construction

A construction done using only a STRAIGHTEDGE. The PONCELET-STEINER THEOREM proves that all constructions possible using a COMPASS and STRAIGHTEDGE are possible using a STRAIGHTEDGE alone, as long as a fixed CIRCLE and its center, two intersecting CIRCLES without their centers, or three nonintersecting CIRCLES are drawn beforehand.

## Steiner's Ellipse

Let  $\alpha' : \beta' : \gamma'$  be the ISOTOMIC CONJUGATE POINT of a point with TRILINEAR COORDINATES  $\alpha : \beta : \gamma$ . The isotomic conjugate of the LINE AT INFINITY having trilinear equation

$$a\alpha + b\beta + c\gamma = 0$$

is

$$\frac{\beta'\gamma'}{a} + \frac{\gamma'\alpha'}{b} + \frac{\alpha'\beta'}{c} = 0,$$

known as Steiner's ellipse (Vandeghen 1965).

see also ISOTOMIC CONJUGATE POINT, LINE AT INFINITY

**Steiner Points**

There are two different types of points known as Steiner points.

The point of CONCURRENCE of the three lines drawn through the VERTICES of a TRIANGLE PARALLEL to the corresponding sides of the first BROCARD TRIANGLE. It lies on the CIRCUMCIRCLE opposite the TARRY POINT and has TRIANGLE CENTER FUNCTION

$$\alpha = bc(a^2 - b^2)(a^2 - c^2).$$

The BRIANCHON POINT for KIEPERT'S PARABOLA is the Steiner point. The LEMOINE POINT  $K$  is the Steiner point of the first BROCARD TRIANGLE. The SIMSON LINE of the Steiner point is PARALLEL to the line  $OK$ , when  $O$  is the CIRCUMCENTER and  $K$  is the LEMOINE POINT.

If triplets of opposites sides on a CONIC SECTION in PASCAL'S THEOREM are extended for all permutations of VERTICES, 60 PASCAL LINES are produced. The 20 points of their 3 by 3 intersections are called Steiner points.

## Steiner's Problem

For what value of  $x$  is  $f(x) = x^{1/x}$  a MAXIMUM? The maximum occurs at  $x = e$ , where

$$f'(x) = x^{-2+1/x}(1 - \ln x) = 0,$$

which gives a maximum of

$$e^{1/e} = 1.444667861 \dots$$

The function has an inflection point at  $x = 0.581933 \dots$ , where

$$f''(x) = x^{-4+1/x}[1 - 3x + (\ln x)(2x - 2 + \ln x)] = 0.$$

see also FERMAT'S PROBLEM

## Steiner Quadruple System

A Steiner quadruple system is a STEINER SYSTEM  $S(t = 3, k = 4, v)$ , where  $S$  is a  $v$ -set and  $B$  is a collection of  $k$ -sets of  $S$  such that every  $t$ -subset of  $S$  is contained in exactly one member of  $B$ . Barrau (1908) established the uniqueness of  $S(3, 4, 8)$ ,

1	2	4	8	3	5	6	7
2	3	5	8	1	4	6	7
3	4	6	8	1	2	5	7
4	5	7	8	1	2	3	6
1	5	6	8	2	3	4	7
2	6	7	8	1	3	4	5
1	3	7	8	2	4	5	6

and  $S(3, 4, 10)$

1	2	4	5	1	2	3	7	1	3	5	8
2	3	5	6	2	3	4	8	2	4	6	9
3	4	6	7	3	4	5	9	3	5	7	0
4	5	7	8	4	5	6	0	1	4	6	8
5	6	8	9	1	5	6	7	2	5	7	9
6	7	9	0	2	6	7	8	3	6	8	0
1	7	8	0	3	7	8	9	1	4	7	9
1	2	8	9	4	8	9	0	2	5	8	0
2	3	9	0	1	5	9	0	1	3	6	9
1	3	4	0	1	2	6	0	2	4	7	0

Fitting (1915) subsequently constructed the cyclic systems  $S(3, 4, 26)$  and  $S(3, 4, 34)$ , and Bays and de Weck

(1935) showed the existence of at least one  $S(3, 4, 14)$ . Hanani (1960) proved that a NECESSARY and SUFFICIENT condition for the existence of an  $S(3, 4, v)$  is that  $v \equiv 2$  or  $4 \pmod{6}$ .

The number of nonisomorphic steiner quadruple systems of orders 8, 10, 14, and 16 are 1, 1, 4 (Mendelsohn and Hung 1972), and at least 31,021 (Lindner and Rosa 1976).

## Steiner's Segment Problem

Given  $n$  points, find the line segments with the shortest possible total length which connect the points. The segments need not necessarily be straight from one point to another.

For three points, if all ANGLES are less than  $120^\circ$ , then the line segments are those connecting the three points to a central point  $P$  which makes the ANGLES  $\langle A \rangle PB$ ,  $\langle B \rangle PC$ , and  $\langle C \rangle PA$  all  $120^\circ$ . If one ANGLE is greater than  $120^\circ$ , then  $P$  coincides with the offending ANGLE.

For four points,  $P$  is the intersection of the two diagonals, but the required minimum segments are not necessarily these diagonals.

A modified version of the problem is, given two points, to find the segments with the shortest total length connecting the points such that each branch point may be connected to only three segments. There is no general solution to this version of the problem.

## Steiner Set

Three sets of three LINES such that each line is incident with two from both other sets.

see also SOLOMON'S SEAL LINES, STEINER POINTS, STEINER TRIPLE SYSTEM

### Steiner Surface

A projection of the VERONESE SURFACE into 3-D (which must contain singularities) is called a Steiner surface. A classification of Steiner surfaces allowing complex parameters and projective transformations was accomplished in the 19th century. The surfaces obtained by restricting to real parameters and transformations were classified into 10 types by Coffman *et al.* (1996). Examples of Steiner surfaces include the ROMAN SURFACE (Coffman type 1) and CROSS-CAP (type 3).

The Steiner surface of type 2 is given by the implicit equation

$$x^2y^2 - x^2z^2 + y^2z^2 - xyz = 0,$$

and can be transformed into the ROMAN SURFACE or CROSS-CAP by a complex projective change of coordinates (but not by a real transformation). It has two pinch points and three double lines and, unlike the ROMAN SURFACE or CROSS-CAP, is not compact in any affine neighborhood.

The Steiner surface of type 4 has the implicit equation

$$y^2 - 2xy^2 - xz^2 + x^2y^2 + x^2z^2 - z^4 = 0,$$

and two of the three double lines of surface 2 coincide along a line where the two noncompact "components" are tangent.

### Steiner System

A Steiner system is a set  $X$  of  $v$  points, and a collection of subsets of  $X$  of size  $k$  (called blocks), such that any  $t$  points of  $X$  are in exactly one of the blocks. The special case  $t = 2$  and  $k = 3$  corresponds to a so-called STEINER TRIPLE SYSTEM. For a PROJECTIVE PLANE,  $v = n^2 + n + 1$ ,  $k = n + 1$ ,  $t = 2$ , and the blocks are simply lines.

see also STEINER QUADRUPLE SYSTEM, STEINER TRIPLE SYSTEM.

### Steiner's Theorem

Let LINES  $x$  and  $y$  join a variable point on a CONIC SECTION to two fixed points on the same CONIC SECTION. Then  $x$  and  $y$  are PROJECTIVELY related.

see also CONIC SECTION, PROJECTION

### Steiner Triple System

Let  $X$  be a set of  $v \geq 3$  elements together with a set  $B$  of 3-subset (triples) of  $X$  such that every 2-SUBSET of  $X$  occurs in exactly one triple of  $B$ . Then  $B$  is called a Steiner triple system and is a special case of a STEINER SYSTEM with  $t = 2$  and  $k = 3$ . A Steiner triple system  $S(v) = S(v, k = 3, \lambda = 1)$  of order  $v$  exists IFF  $v \equiv 1, 3 \pmod{6}$  (Kirkman 1847). In addition, if Steiner triple systems  $S_1$  and  $S_2$  of orders  $v_1$  and  $v_2$  exist, then so does a Steiner triple system  $S$  of order  $v_1v_2$  (Ryser 1963, p. 101).

Examples of Steiner triple systems  $S(v)$  of small orders  $v$  are

$$S_3 = \{\{1, 2, 3\}\}$$

$$S_7 = \{\{1, 2, 4\}, \{2, 3, 5\}, \{3, 4, 6\}, \{4, 5, 7\}, \\ \{5, 6, 1\}, \{6, 7, 2\}, \{7, 1, 3\}\}$$

$$S_9 = \{\{1, 2, 3\}, \{4, 5, 6\}, \{7, 8, 9\}, \{1, 4, 7\}, \\ \{2, 5, 8\}, \{3, 6, 9\}, \{1, 5, 9\}, \{2, 6, 7\}\}.$$

The number of nonisomorphic Steiner triple systems  $S(v)$  of orders  $v = 7, 9, 13, 15, 19, \dots$  (i.e.,  $6k + 1, 3$ ) are 1, 1, 20, 80,  $> 1.1 \times 10^9, \dots$  (Colbourn and Dinitz 1996, pp. 14–15; Sloane's A030129).  $S(7)$  is the same as the finite PROJECTIVE PLANE of order 2.  $S(9)$  is a finite AFFINE PLANE which can be constructed from the array

$$\begin{array}{ccc} a & b & c \\ d & e & f \\ g & h & i \end{array}$$

One of the two  $S(13)$ s is a finite HYPERBOLIC PLANE. The 80 Steiner triple systems  $S(15)$  have been studied by Tonchev and Weishaar (1997). There are more than  $1.1 \times 10^9$  Steiner triple systems of order 19 (Stinson and Ferch 1985; Colbourn and Dinitz 1996, p. 15).

### Steinerian Curve

The LOCUS of points whose first POLARS with regard to the curves of a linear net have a common point. It is also the LOCUS of points of CONCURRENCE of line POLARS of points of the JACOBIAN CURVE. It passes through all points common to all curves of the system and is of order  $3(n-1)^2$ .

see also CAYLEYIAN CURVE, JACOBIAN CURVE

### References

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 150, 1959.

### Steinhaus-Moser Notation

A NOTATION for LARGE NUMBERS defined by Steinhaus (1983, pp. 28–29). In this notation,  $\triangle_n$  denotes  $n^n$ ,  $\square_n$  denotes " $n$  in  $n$  TRIANGLES," and  $\odot_n$  denotes " $n$  in  $n$  SQUARES." A modified version due to Moser eliminates the circle notation, continuing instead with POLYGONS of ever increasing size, so  $n$  in a PENTAGON is  $n$  with  $n$  SQUARES around it, etc.

see also CIRCLE NOTATION, LARGE NUMBER, MEGA, MOSER

### References

Steinhaus, H. *Mathematical Snapshots*, 3rd American ed. New York: Oxford University Press, 1983.

### Steinitz's Theorem

A GRAPH  $G$  is the edge graph of a POLYHEDRON IFF  $G$  is a SIMPLE, PLANAR GRAPH which is 3-connected.

see also PLANAR GRAPH, SIMPLE GRAPH

### Steinmetz Solid

The solid common to two (or three) right circular CYLINDERS of equal RADII intersecting at RIGHT ANGLES is called the Steinmetz solid. (Two CYLINDERS intersecting at RIGHT ANGLES are sometimes called a BICYLINDER, and three intersecting CYLINDERS a TRICYLINDER.)

The VOLUME common to two intersecting right CYLINDERS of RADIUS  $r$  is

$$V_2(r, r) = \frac{16}{3}r^3. \quad (1)$$

If the two right CYLINDERS are of *different* RADII  $a$  and  $b$  with  $a > b$ , then the VOLUME common to them is

$$V_2(a, b) = \frac{8}{3}a[(a^2 + b^2)E(k) - (a^2 - b^2)K(k)], \quad (2)$$

where  $K(k)$  is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND,  $E(k)$  is the complete ELLIPTIC INTEGRAL OF THE SECOND KIND, and  $k \equiv b/a$  is the MODULUS.

The curves of intersection of two cylinders of RADII  $a$  and  $b$ , shown above, are given by the parametric equations

$$x(t) = a \cos t \quad (3)$$

$$y(t) = a \sin t \quad (4)$$

$$z(t) = \pm \sqrt{b^2 - a^2 \sin^2 t} \quad (5)$$

(Gray 1993).

The VOLUME common to two ELLIPTIC CYLINDERS

$$\frac{x^2}{a^2} + \frac{z^2}{c^2} = 1 \quad \frac{y^2}{b^2} + \frac{z^2}{c'^2} = 1 \quad (6)$$

with  $c < c'$  is

$$V_2(a, c; b, c') = \frac{8ab}{3c} [(c'^2 + c^2)E(k) - (c'^2 - c^2)K(k)], \quad (7)$$

where  $k = c/c'$  (Bowman 1961, p. 34).

For three CYLINDERS of RADII  $r$  intersecting at RIGHT ANGLES, the VOLUME of intersection is

$$V_3(r, r, r) = 8(2 - \sqrt{2})r^3. \quad (8)$$

see also BICYLINDER, CYLINDER

**Stella Octangula**

A POLYHEDRON COMPOUND composed of a TETRAHEDRON and its RECIPROCAL (a second TETRAHEDRON rotated  $180^\circ$  with respect to the first). The stella octangula is also called a STELLATED TETRAHEDRON. It can be constructed using the following NET by cutting along the solid lines, folding back along the plain lines, and folding forward along the dotted lines.

Another construction builds a single TETRAHEDRON, then attaches four tetrahedral caps, one to each face.

The edges of the two tetrahedra form the 12 DIAGONALS of a CUBE. The solid common to both tetrahedra is an OCTAHEDRON (Ball and Coxeter 1987).

**Stella Octangula Number**

A FIGURATE NUMBER of the form,

$$StOct_n = O_n + 8T_{n-1} = n(2n^2 - 1).$$

The first few are 1, 14, 51, 124, 245, ... (Sloane's A007588). The GENERATING FUNCTION for the stella octangula numbers is

$$\frac{x(x^2 + 10x + 1)}{(x - 1)^4} = x + 14x^2 + 51x^3 + 124x^4 + \dots$$

**References**

 Sloane, N. J. A. Sequence A007588/M4932 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Stellated Polyhedron**

A convex regular POLYHEDRON. Stellated polyhedra include the KEPLER-POINSOT SOLIDS, which consist of three DODECAHEDRON STELLATIONS and one of the ICOSAEDRON STELLATIONS. Coxeter (1982) shows that 59 ICOSAEDRON STELLATIONS exist. The CUBE and the TETRAHEDRON cannot be stellated. The OCTAHEDRON has only one stellation, the STELLA OCTANGULA which is a compound of two TETRAHEDRA.

There are therefore a total of  $3 + 1 + (59 - 1) + 1 = 63$  stellated POLYHEDRA, although some are COMPOUND POLYHEDRA and therefore not UNIFORM POLYHEDRA. The set of all possible EDGES of the stellations can be obtained by finding all intersections on the facial planes.

### Stem-and-Leaf Diagram

The "stem" is a column of the data with the last digit removed. The final digits of each column are placed next to each other in a row next to the appropriate column. Then each row is sorted in numerical order. This diagram was invented by John Tukey.

### Step Function

A function on the REALS  $\mathbb{R}$  is a step function if it can be written as a finite linear combination of semi-open intervals  $[a, b) \subseteq \mathbb{R}$ . Therefore, a step function  $f$  can be written as

$$f(x) = \alpha_1 f_1(x) + \cdots + \alpha_n f_n(x),$$

where  $\alpha_i \in \mathbb{R}$ ,  $f_i(x) = 1$  if  $x \in [a_i, b_i)$  and 0 otherwise, for  $i = 1, \dots, n$ .

### Steradian

The unit of SOLID ANGLE. The SOLID ANGLE corresponding to all of space being subtended is  $4\pi$  steradian.

see also RADIAN, SOLID ANGLE

### Stereogram

A plane image or pair of 2-D images which, when appropriately viewed using both eyes, produces an image which appears to be three-dimensional. By taking a pair of photographs from slightly different angles and then allowing one eye to view each image, a stereogram is not difficult to produce.

Amazingly, it turns out that the 3-D effect can be produced by both eyes looking at a *single* image by defocusing the eyes at a certain distance. Such stereograms are called "random-dot stereograms."

## Stereographic Projection

A MAP PROJECTION in which GREAT CIRCLES are CIRCLES and LOXODROMES are LOGARITHMIC SPIRALS.

$$x = k \cos \phi \sin(\lambda - \lambda_0) \quad (1)$$

$$y = k[\cos \phi_1 \sin \phi - \sin \phi_1 \cos \phi \cos(\lambda - \lambda_0)], \quad (2)$$

where

$$k = \frac{2}{1 + \sin \phi_1 \sin \phi + \cos \phi_1 \cos \phi \cos(\lambda - \lambda_0)}. \quad (3)$$

The inverse FORMULAS are given by

$$\phi = \sin^{-1} \left( \cos c \sin \phi_1 + \frac{y \sin c \cos \phi_1}{\rho} \right) \quad (4)$$

$$\lambda = \lambda_0 + \tan^{-1} \left( \frac{x \sin c}{\rho \cos \phi_1 \cos c - y \sin \phi_1 \sin c} \right), \quad (5)$$

where

$$\rho = \sqrt{x^2 + y^2} \quad (6)$$

$$c = 2 \tan^{-1} \left( \frac{1}{2} \rho \right). \quad (7)$$

## Stick Number

Let the stick number  $s(K)$  of a KNOT  $K$  be the least number of straight sticks needed to make a KNOT  $K$ . The smallest stick number of any KNOT is  $s(T) = 6$ , where  $T$  is the TREFOIL KNOT. If  $J$  and  $K$  are KNOTS, then

$$s(J + K) \leq s(J) + s(K) + 1.$$

For a nontrivial KNOT  $K$ , let  $c(K)$  be the CROSSING NUMBER (i.e., the least number of crossings in any projection of  $K$ ). Then

$$\frac{1}{2}[5 + \sqrt{25 + 8(c(K) - 2)}] \leq s(K) \leq 2c(K).$$

The following table gives the stick number for some common knots.

Knot	$s$
trefoil knot	6
Whitehead link	8

### Stickelberger Relation

Let  $P$  be a PRIME IDEAL in  $D_m$  not containing  $m$ . Then

$$(\Phi(P)) = P \sum t \sigma_t^{-1},$$

where the sum is over all  $1 \leq t < m$  which are RELATIVELY PRIME to  $m$ . Here  $D_m$  is the RING of integers in  $\mathbb{Q}(\zeta_m)$ ,  $\Phi(P) = g(P)^m$ , and other quantities are defined by Ireland and Rosen (1990).

see also PRIME IDEAL

#### References

### Stiefel Manifold

The Stiefel manifold of ORTHONORMAL  $k$ -frames in  $\mathbb{R}^n$  is the collection of vectors  $(v_1, \dots, v_k)$  where  $v_i$  is in  $\mathbb{R}^n$  for all  $i$ , and the  $k$ -tuple  $(v_1, \dots, v_k)$  is ORTHONORMAL. This is a submanifold of  $\mathbb{R}^{nk}$ , having DIMENSION  $nk - (k + 1)k/2$ .

Sometimes the "orthonormal" condition is dropped in favor of the mildly weaker condition that the  $k$ -tuple  $(v_1, \dots, v_k)$  is linearly independent. Usually, this does not affect the applications since Stiefel manifolds are usually considered only during HOMOTOPY THEORETIC considerations. With respect to HOMOTOPY THEORY, the two definitions are more or less equivalent since GRAM-SCHMIDT ORTHONORMALIZATION gives rise to a smooth deformation retraction of the second type of Stiefel manifold onto the first.

see also GRASSMANN MANIFOLD

### Stiefel-Whitney Class

The  $i$ th Stiefel-Whitney class of a REAL VECTOR BUNDLE (or TANGENT BUNDLE or a REAL MANIFOLD) is in the  $i$ th cohomology group of the base SPACE involved. It is an OBSTRUCTION to the existence of  $(n - i + 1)$  REAL linearly independent VECTOR FIELDS on that VECTOR BUNDLE, where  $n$  is the dimension of the FIBER. Here, OBSTRUCTION means that the  $i$ th Stiefel-Whitney class being NONZERO implies that there do not exist  $(n - i + 1)$  everywhere linearly dependent VECTOR FIELDS (although the Stiefel-Whitney classes are not always the OBSTRUCTION).

In particular, the  $n$ th Stiefel-Whitney class is the obstruction to the existence of an everywhere NONZERO VECTOR FIELD, and the first Stiefel-Whitney class of a MANIFOLD is the obstruction to orientability.

see also CHERN CLASS, OBSTRUCTION, PONTRYAGIN CLASS, STIEFEL-WHITNEY NUMBER

### Stiefel-Whitney Number

The Stiefel-Whitney number is defined in terms of the STIEFEL-WHITNEY CLASS of a MANIFOLD as follows. For any collection of STIEFEL-WHITNEY CLASSES such that their cup product has the same DIMENSION as the MANIFOLD, this cup product can be evaluated on the MANIFOLD's FUNDAMENTAL CLASS. The resulting number is called the PONTRYAGIN NUMBER for that combination of Pontryagin classes.

The most important aspect of Stiefel-Whitney numbers is that they are COBORDISM invariant. Together, PONTRYAGIN and Stiefel-Whitney numbers determine an oriented MANIFOLD's COBORDISM class.

see also CHERN NUMBER, PONTRYAGIN NUMBER, STIEFEL-WHITNEY CLASS

### Stieltjes Constants

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Expanding the RIEMANN ZETA FUNCTION about  $z = 1$  gives

$$\zeta(z) = \frac{1}{z-1} + \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \gamma_n (z-1)^n, \quad (1)$$

where

$$\gamma_n \equiv \lim_{m \rightarrow \infty} \left[ \sum_{k=1}^m \frac{(\ln k)^n}{k} - \frac{(\ln m)^{n+1}}{n+1} \right]. \quad (2)$$

An alternative definition is given by

$$\gamma'_n \equiv \frac{(-1)^n}{n!} \gamma_n. \quad (3)$$

The case  $n = 0$  gives the EULER-MASCHERONI CONSTANT  $\gamma$ . The first few numerical values are given in the following table.

$n$	$\gamma_n$
0	0.5772156649
1	-0.07281584548
2	-0.009690363192
3	0.002053834420
4	0.002325370065
5	0.0007933238173

Briggs (1955-1956) proved that there infinitely many  $\gamma_n$  of each SIGN. Berndt (1972) gave upper bounds of

$$|\gamma_n| < \begin{cases} \frac{4(n-1)!}{\pi^n} & \text{for } n \text{ even} \\ \frac{2(n-1)!}{\pi^n} & \text{for } n \text{ odd.} \end{cases} \quad (4)$$

Vacca (1910) proves that the EULER-MASCHERONI CONSTANT may be expressed as

$$\gamma = \sum_{k=1}^{\infty} \frac{(-1)^k}{k} [\lg k], \quad (5)$$

where  $[x]$  is the FLOOR FUNCTION. Hardy (1912) gave the FORMULA

$$\frac{2\gamma_1}{\ln 2} = \sum_{k=1}^{\infty} \frac{(-1)^k}{k} [2 \lg k - [\lg(2k)]] [\lg k]. \quad (6)$$

Kluyver (1927) gave similar series for  $\gamma_n$  with  $n > 1$ .

A set of constants related to  $\gamma_n$  is

$$\delta_n \equiv \lim_{m \rightarrow \infty} \left[ \sum_{k=1}^m (\ln k)^n - \int_1^m (\ln x)^n dx - \frac{1}{2} (\ln m)^n \right] \quad (7)$$

(Sitaramachandrarao 1986, Lehmer 1988).

## Stieltjes Integral

The Stieltjes integral is a generalization of the RIEMANN INTEGRAL. Let  $f(x)$  and  $\alpha(x)$  be real-values bounded functions defined on a CLOSED INTERVAL  $[a, b]$ . Take a partition of the INTERVAL

$$a = x_0 < x_1 < x_2, \dots < x_{n-1} < x_n = b, \quad (1)$$

and consider the Riemann sum

$$\sum_{i=0}^{n-1} f(\xi_i) [\alpha(x_{i+1}) - \alpha(x_i)] \quad (2)$$

with  $\xi_i \in [x_i, x_{i+1}]$ . If the sum tends to a fixed number  $I$  as  $\max(x_{i+1} - x_i) \rightarrow 0$ , then  $I$  is called the Stieltjes integral, or sometimes the RIEMANN-STIELTJES INTEGRAL. The Stieltjes integral of  $P$  with respect to  $F$  is denoted

$$\int P(x) dF(x), \quad (3)$$

where

$$\int P(x) dF(x) = \begin{cases} \int f(x) dx & \text{for } x \text{ continuous} \\ \sum_x f(x) & \text{for } x \text{ discrete.} \end{cases} \quad (4)$$

If  $P$  and  $F$  have a common point of discontinuity, then the integral does not exist. However, if the Stieltjes integral exists and  $F$  has a derivative  $F'$ , then

$$\int P(x) dF(x) = \int P(x) F'(x) dx. \quad (5)$$

For enumeration of many of the integral's properties, see Dresher (1981, p. 105).

### Stieltjes-Wigert Polynomial

Orthogonal POLYNOMIALS associated with WEIGHTING FUNCTION

$$w(x) = \pi^{-1/2} k \exp(-k^2 \ln^2 x) = \pi^{-1/2} k x^{-k^2 \ln x} \quad (1)$$

for  $x \in (0, \infty)$  and  $k > 0$ . Using

$$\begin{bmatrix} n \\ \nu \end{bmatrix} = \frac{(1-q^n)(1-q^{n-1}) \cdots (1-q^{n-\nu+1})}{(1-q)(1-q^2) \cdots (1-q^\nu)} \quad (2)$$

where  $0 < \nu < n$ ,

$$\begin{bmatrix} n \\ 0 \end{bmatrix} = \begin{bmatrix} n \\ n \end{bmatrix} = 1, \quad (3)$$

and

$$q = \exp[-(2k^2)^{-1}]. \quad (4)$$

Then

$$p_n(x) = (-1)^n q^{n/2+1/4} [(1-q)(1-q^2) \cdots (1-q^n)]^{-1/2} \times \sum_{\nu=0}^n \begin{bmatrix} n \\ \nu \end{bmatrix} q^{\nu^2} (-q^{1/2} x)^\nu \quad (5)$$

for  $n > 0$  and

$$p_0(x) = q^{1/4}. \quad (6)$$

### Stirling's Approximation

Stirling's approximation gives an approximate value for the FACTORIAL function  $n!$  or the GAMMA FUNCTION  $\Gamma(n)$  for  $n \gg 1$ . The approximation can most simply be derived for  $n$  an INTEGER by approximating the sum over the terms of the FACTORIAL with an INTEGRAL, so that

$$\begin{aligned} \ln n! &= \ln 1 + \ln 2 + \cdots + \ln n = \sum_{k=1}^n \ln k \approx \int_1^n \ln x \, dx \\ &= [x \ln x - x]_1^n = n \ln n - n + 1 \approx n \ln n - n. \end{aligned} \quad (1)$$

The equation can also be derived using the integral definition of the FACTORIAL,

$$n! = \int_0^\infty e^{-x} x^n \, dx. \quad (2)$$

Note that the derivative of the LOGARITHM of the integrand can be written

$$\frac{d}{dx} \ln(e^{-x} x^n) = \frac{d}{dx} (n \ln x - x) = \frac{n}{x} - 1. \quad (3)$$

The integrand is sharply peaked with the contribution important only near  $x = n$ . Therefore, let  $x \equiv n + \xi$  where  $\xi \ll n$ , and write

$$\ln(x^n e^{-x}) = n \ln x - x = n \ln(n + \xi) - (n + \xi). \quad (4)$$

Now,

$$\begin{aligned} \ln(n + \xi) &= \ln \left[ n \left( 1 + \frac{\xi}{n} \right) \right] = \ln n + \ln \left( 1 + \frac{\xi}{n} \right) \\ &= \ln n + \frac{\xi}{n} - \frac{1}{2} \frac{\xi^2}{n^2} + \cdots, \end{aligned} \quad (5)$$

so

$$\begin{aligned} \ln(x^n e^{-x}) &= n \ln(n + \xi) - (n + \xi) \\ &= n \ln n + \xi - \frac{1}{2} \frac{\xi^2}{n} - n - \xi + \cdots \\ &= n \ln n - n - \frac{\xi^2}{2n} + \cdots \end{aligned} \quad (6)$$

Taking the EXPONENTIAL of each side then gives

$$x^n e^{-x} \approx e^{n \ln n} e^{-n} e^{-\xi^2/2n} = n^n e^{-n} e^{-\xi^2/2n}. \quad (7)$$

Plugging into the integral expression for  $n!$  then gives

$$\begin{aligned} n! &\approx \int_{-n}^{\infty} n^n e^{-n} e^{-\xi^2/2n} d\xi \approx n^n e^{-n} \int_{-\infty}^{\infty} e^{-\xi^2/2n} d\xi \\ &= n^n. \end{aligned} \quad (8)$$

Evaluating the integral gives

$$n! \approx n^n e^{-n} \sqrt{2\pi n}, \quad (9)$$

$$\approx \sqrt{2\pi} n^{n+1/2} e^{-n}. \quad (10)$$

Taking the LOGARITHM of both sides then gives

$$\ln n! \approx n \ln n - n + \frac{1}{2} \ln(2\pi n) = (n + \frac{1}{2}) \ln n - n + \frac{1}{2} \ln(2\pi). \quad (11)$$

This is STIRLING'S SERIES with only the first term retained and, for large  $n$ , it reduces to Stirling's approximation

$$\ln n! \approx n \ln n - n. \quad (12)$$

Gosper notes that a better approximation to  $n!$  (i.e., one which approximates the terms in STIRLING'S SERIES instead of truncating them) is given by

$$n! \approx \sqrt{(2n + \frac{1}{3})\pi} n^n e^{-n}. \quad (13)$$

This also gives a much closer approximation to the FACTORIAL of 0,  $0! = 1$ , yielding  $\sqrt{\pi/3} \approx 1.02333$  instead of 0 obtained with the conventional Stirling approximation.

see also STIRLING'S SERIES

**Stirling Cycle Number**

see STIRLING NUMBER OF THE FIRST KIND

**Stirling's Finite Difference Formula**

$$f_p = f_0 + \frac{1}{2}p(\delta_{1/2} + \delta_{-1/2}) + \frac{1}{2}p^2\delta_0^2 \\ + S_3(\delta_{1/2}^2 + \delta_{-1/2}^2) + S_4\delta_0^4 + \dots,$$

for  $p \in [-1/2, 1/2]$ , where  $\delta$  is the CENTRAL DIFFERENCE and

$$S_{2n+1} = \frac{1}{2} \binom{p+n}{2n+1} \\ S_{2n+2} = \frac{p}{2n+2} \binom{p+n}{2n+1},$$

with  $\binom{n}{k}$  a BINOMIAL COEFFICIENT.

see also CENTRAL DIFFERENCE, STEFFENSON'S FORMULA

**Stirling's Formula**

see STIRLING'S SERIES

**Stirling Number of the First Kind**

The definition of the (signed) Stirling number of the first kind is a number  $S_n^{(m)}$  such that the number of permutations of  $n$  elements which contain exactly  $m$  CYCLES is

$$(-1)^{n-m} S_n^{(m)}. \quad (1)$$

This means that  $S_n^{(m)} = 0$  for  $m > n$  and  $S_n^{(n)} = 1$ . The GENERATING FUNCTION is

$$x(x-1)\cdots(x-n+1) = \sum_{m=0}^n S_n^{(m)} x^m. \quad (2)$$

This is the Stirling number of the first kind returned by the *Mathematica*® (Wolfram Research, Champaign, IL) command `StirlingS1[n,m]`. The triangle of signed Stirling numbers of the first kind is

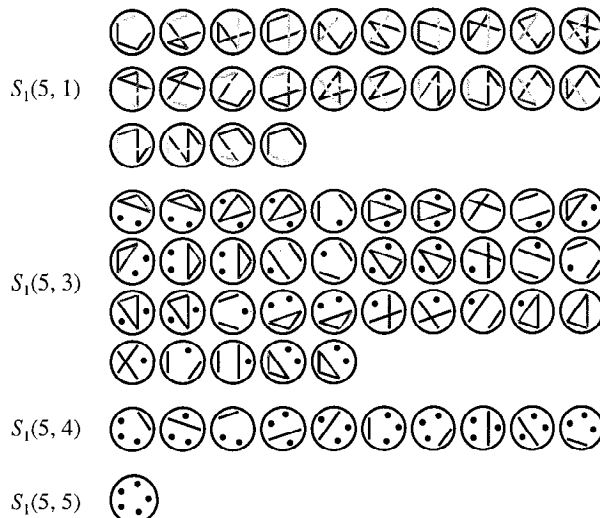

$$\begin{array}{ccccccc} & & & & 1 & & \\ & & & -1 & 1 & & \\ & 2 & -3 & 1 & & & \\ -6 & 11 & 6 & 1 & & & \\ 24 & -50 & 35 & -10 & 1 & & \end{array}$$

(Sloane's A008275).

The NONNEGATIVE version simply gives the number of PERMUTATIONS of  $n$  objects having  $m$  CYCLES (with

*Stirling Number of the First Kind*

cycles in opposite directions counted as distinct) and is obtained by taking the ABSOLUTE VALUE of the signed version. The nonnegative Stirling number of the first kind is denoted  $S_1(n, m) = |S_n^{(m)}|$  or  $\left[ \begin{smallmatrix} n \\ m \end{smallmatrix} \right]$ . Diagrams illustrating  $S_1(5, 1) = 24$ ,  $S_1(5, 3) = 35$ ,  $S_1(5, 4) = 10$ , and  $S_1(5, 5) = 1$  (Dickau) are shown below.

The nonnegative Stirling numbers of the first kind satisfy the curious identity

$$\sum_{n=1}^{\infty} \left[ \sum_{k=0}^{n-2} \frac{(e^x - x - 1)^{k+1} S_1(n, n-k)}{(k+1)!} \right] e^{-x^n} = \ln(x+1) \quad (3)$$

(Gosper) and have the GENERATING FUNCTION

$$(1+x)(1+2x)\cdots(1+nx) = \sum_{k=1}^n S_1(n, m) x^k \quad (4)$$

and satisfy

$$1(n+1, k) = nS_1(n, k) + S_1(n, k-1). \quad (5)$$

The Stirling numbers can be generalized to nonintegral arguments (a sort of "Stirling polynomial") using the identity

$$\frac{\Gamma(j+h)}{j^h \Gamma(j)} = \sum_{k=0}^{\infty} \frac{S_1(h, h-k)}{j^k} \\ = 1 + \frac{(h-1)h}{2j} + \frac{(h-2)(3h-1)(h-1)h}{24j^2} \\ + \frac{(h-3)(h-2)(h-1)^2 h^2}{48j^3} + \dots, \quad (6)$$

which is a generalization of an ASYMPTOTIC SERIES for a ratio of GAMMA FUNCTIONS  $\Gamma(j+1/2)/\Gamma(j)$  (Gosper). see also CYCLE (PERMUTATION), HARMONIC NUMBER, PERMUTATION, STIRLING NUMBER OF THE SECOND KIND

### Stirling Number of the Second Kind

The number of ways of partitioning a set of  $n$  elements into  $m$  nonempty SETS (i.e.,  $m$  BLOCKS), also called a STIRLING SET NUMBER. For example, the SET  $\{1, 2, 3\}$  can be partitioned into three SUBSETS in one way:  $\{\{1\}, \{2\}, \{3\}\}$ ; into two SUBSETS in three ways:  $\{\{1, 2\}, \{3\}\}$ ,  $\{\{1, 3\}, \{2\}\}$ , and  $\{\{1\}, \{2, 3\}\}$ ; and into one SUBSET in one way:  $\{\{1, 2, 3\}\}$ .

The Stirling numbers of the second kind are denoted  $s_n^{(m)}$ ,  $S_2(n, m)$ ,  $s(n, m)$ , or  $\left\{ \begin{smallmatrix} n \\ m \end{smallmatrix} \right\}$ , so the Stirling numbers of the second kind for three elements are

$$s(3, 1) = 1 \quad (1)$$

$$s(3, 2) = 3 \quad (2)$$

$$s(3, 3) = 1. \quad (3)$$

Since a set of  $n$  elements can only be partitioned in a single way into 1 or  $n$  SUBSETS,

$$s(n, 1) = s(n, n) = 1. \quad (4)$$

The triangle of Stirling numbers of the second kind is

$$\begin{array}{ccccccc} & & & & 1 & & \\ & & & 1 & 1 & & \\ & & 1 & 3 & 1 & & \\ & 1 & 7 & 6 & 1 & & \\ 1 & 15 & 25 & 10 & 1 & & \\ 1 & 31 & 90 & 65 & 15 & 1 & \end{array}$$

(Sloane's A008277).

The Stirling numbers of the second kind can be computed from the sum

$$s(n, k) = \frac{1}{k!} \sum_{i=0}^{k-1} (-1)^i \binom{k}{i} (k-i)^n, \quad (5)$$

with  $\binom{n}{k}$  a BINOMIAL COEFFICIENT, or the GENERATING FUNCTIONS

$$x^n = \sum_{m=0}^n s(n, m) x(x-1) \cdots (x-m+1), \quad (6)$$

$$\sum_{n \geq k} s(n, k) \frac{x^n}{n!} = \frac{1}{k!} (e^x - 1)^k, \quad (7)$$

and

$$\frac{1}{(1-x)(1-2x) \cdots (1-kx)} = \sum_{n=1}^k s(n, k) x^n. \quad (8)$$

The following diagrams (Dickau) illustrate the definition of the Stirling numbers of the second kind  $s(n, m)$  for  $n = 3$  and 4.

Stirling numbers of the second kind obey the RECURSIVE RELATIONS

$$s(n, k) = s(n-1, k-1) + ks(n-1, k). \quad (9)$$

An identity involving Stirling numbers of the second kind is

$$f(m, n) \equiv \sum_{k=1}^{\infty} k^n \left( \frac{m}{m+1} \right)^k = (m+1) \sum_{k=1}^m k! s(n, k) m^k. \quad (10)$$

It turns out that  $f(1, n)$  can have only 0, 2, or 6 as a last DIGIT (Riskin 1995).

### Stirling's Series

THE ASYMPTOTIC SERIES for the GAMMA FUNCTION is given by

$$\Gamma(z) = e^{-z} z^{z-1/2} \sqrt{2\pi} \left( 1 + \frac{1}{12z} + \frac{1}{288z^2} - \frac{139}{51840z^3} - \frac{571}{2488320z^4} + \dots \right) \quad (1)$$

(Sloane's A001163 and A001164). The series for  $z!$  is obtained by adding an additional factor of  $z$ ,

$$z! = \Gamma(z+1) = e^{-z} z^{z+1/2} \sqrt{2\pi} \left( 1 + \frac{1}{12z} + \frac{1}{288z^2} - \frac{139}{51840z^3} - \frac{571}{2488320z^4} + \dots \right). \quad (2)$$

The expansion of  $\ln \Gamma(z)$  is what is usually called Stirling's series. It is given by the simple analytic expression

$$\begin{aligned} \ln \Gamma(z) &= \sum_{n=1}^{\infty} \frac{B_{2n}}{2n(2n-1)z^{2n-1}} \\ &= \frac{1}{2} \ln(2\pi) + \left(z + \frac{1}{2}\right) \ln z - z + \frac{1}{12z} - \frac{1}{360z^3} + \frac{1}{1260z^5} - \dots, \end{aligned} \quad (3)$$

where  $B_n$  is a BERNOULLI NUMBER.

see also BERNOULLI NUMBER,  $K$ -FUNCTION, STIRLING'S APPROXIMATION

see MALLIAVIN CALCULUS

### Stochastic Group

THE GROUP of all nonsingular  $n \times n$  STOCHASTIC MATRICES over a FIELD  $F$ . It is denoted  $S(n, F)$ . If  $p$  is PRIME and  $F$  is the GALOIS FIELD of ORDER  $q = p^m$ ,  $S(n, q)$  is written instead of  $S(n, F)$ . Particular examples include

$$\begin{aligned} S(2, 2) &= \mathbb{Z}_2 \\ S(2, 3) &= S_3 \\ S(2, 4) &= A_4 \\ S(3, 2) &= S_4 \\ S(2, 5) &= \mathbb{Z}_4 \times_{\theta} \mathbb{Z}_5, \end{aligned}$$

where  $\mathbb{Z}_2$  is an ABELIAN GROUP,  $S_n$  are SYMMETRIC GROUPS on  $n$  elements, and  $\times_{\theta}$  denotes the semidirect product with  $\theta: \mathbb{Z}_4 \rightarrow \text{Aut}(\mathbb{Z}_5)$  (Poole 1995).

see also STOCHASTIC MATRIX

### References

### Stochastic Matrix

A Stochastic matrix is the transition matrix for a finite MARKOV CHAIN, also called a MARKOV MATRIX. Elements of the matrix must be REAL NUMBERS in the CLOSED INTERVAL  $[0, 1]$ .

A completely independent type of stochastic matrix is defined as a SQUARE MATRIX with entries in a FIELD  $F$  such that the sum of elements in each column equals 1. There are two nonsingular  $2 \times 2$  STOCHASTIC MATRICES over  $\mathbb{Z}_2$  (i.e., the integers mod 2),

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

There are six nonsingular stochastic  $3 \times 3$  MATRICES over  $\mathbb{Z}_3$ ,

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 2 & 1 \\ 2 & 0 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 2 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 2 \\ 1 & 2 \end{bmatrix}, \begin{bmatrix} 1 & 2 \\ 0 & 2 \end{bmatrix}.$$

In fact, the set  $S$  of all nonsingular stochastic  $n \times n$  matrices over a FIELD  $F$  forms a GROUP under MATRIX MULTIPLICATION. This GROUP is called the STOCHASTIC GROUP.

### Stochastic Resonance

A stochastic resonance is a phenomenon in which a nonlinear system is subjected to a periodic modulated signal so weak as to be normally undetectable, but it becomes detectable due to resonance between the weak deterministic signal and stochastic NOISE. The earliest definition of stochastic resonance was the maximum of the output signal strength as a function of NOISE (Bulsara and Gammaitoni 1996).

### Stokes' Theorem

For  $w$  a DIFFERENTIAL  $(n-1)$ -FORM with compact support on an oriented  $n$ -dimensional MANIFOLD  $M$ ,

$$\int_M dw = \int_{\partial M} w, \quad (1)$$

where  $dw$  is the EXTERIOR DERIVATIVE of the differential form  $w$ . This connects to the "standard" GRADIENT, CURL, and DIVERGENCE THEOREMS by the following relations. If  $f$  is a function on  $\mathbb{R}^3$ ,

$$\text{grad}(f) = c^{-1} df, \quad (2)$$

where  $c : \mathbb{R}^3 \rightarrow \mathbb{R}^{3*}$  (the dual space) is the duality isomorphism between a VECTOR SPACE and its dual, given by the Euclidean INNER PRODUCT on  $\mathbb{R}^3$ . If  $f$  is a VECTOR FIELD on a  $\mathbb{R}^3$ ,

$$\text{div}(f) = *d^*c(f), \quad (3)$$

where  $*$  is the HODGE STAR operator. If  $f$  is a VECTOR FIELD on  $\mathbb{R}^3$ ,

$$\text{curl}(f) = c^{-1} *dc(f). \quad (4)$$

With these three identities in mind, the above Stokes' theorem in the three instances is transformed into the GRADIENT, CURL, and DIVERGENCE THEOREMS respectively as follows. If  $f$  is a function on  $\mathbb{R}^3$  and  $\gamma$  is a curve in  $\mathbb{R}^3$ , then

$$\int_\gamma \text{grad}(f) \cdot d\mathbf{l} = \int_\gamma df = f(\gamma(1)) - f(\gamma(0)), \quad (5)$$

which is the GRADIENT THEOREM. If  $f : \mathbb{R}^3 \rightarrow \mathbb{R}^3$  is a VECTOR FIELD and  $M$  an embedded compact 3-manifold with boundary in  $\mathbb{R}^3$ , then

$$\int_{\partial M} f \cdot dA = \int_{\partial M} *cf = \int_M d*cf = \int_M \operatorname{div}(f) dV, \quad (6)$$

which is the DIVERGENCE THEOREM. If  $f$  is a VECTOR FIELD and  $M$  is an oriented, embedded, compact 2-MANIFOLD with boundary in  $\mathbb{R}^3$ , then

$$\int_{\partial M} f dl = \int_{\partial M} cf = \int_M dc(f) = \int_M \operatorname{curl}(f) \cdot dA, \quad (7)$$

which is the CURL THEOREM.

Physicists generally refer to the CURL THEOREM

$$\int_S (\nabla \times \mathbf{F}) \cdot d\mathbf{a} = \int_{\partial S} \mathbf{F} \cdot d\mathbf{s} \quad (8)$$

as Stokes' theorem.

see also CURL THEOREM, DIVERGENCE THEOREM, GRADIENT THEOREM

### Stolarsky Array

A INTERSPERSION array given by

### Stolarsky-Harborth Constant

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let  $b(k)$  be the number of 1s in the BINARY expression of  $k$ . Then the number of ODD BINOMIAL COEFFICIENTS  $\binom{k}{j}$  where  $0 \leq j \leq k$  is  $2^{b(k)}$  (Glaisher 1899, Fine 1947).

The number of ODD elements in the first  $n$  rows of PASCAL'S TRIANGLE is

$$f(n) = \sum_{k=0}^{n-1} 2^{b(k)}. \quad (1)$$

This function is well approximated by  $n^\theta$ , where

$$\theta \equiv \frac{\ln 3}{\ln 2} = 1.58496\dots \quad (2)$$

Stolarsky and Harborth showed that

$$0.812556 \leq \liminf_{n \rightarrow \infty} \frac{f(n)}{n^\theta} < 0.812557 < \limsup_{n \rightarrow \infty} \frac{f(n)}{n^\theta} = 1. \quad (3)$$

The value

$$SH = \liminf_{n \rightarrow \infty} \frac{f(n)}{n^\theta} \quad (4)$$

is called the Stolarsky-Harborth constant.

### Stolarsky's Inequality

If  $0 \leq g(x) \leq 1$  and  $g$  is nonincreasing on the INTERVAL  $[0,1]$ , then for all possible values of  $a$  and  $b$ ,

$$\int_0^1 g(x^{1/(a+b)}) dx \geq \int_0^1 g(x^{1/a}) dx \int_0^1 g(x^{1/b}) dx.$$

### Stomachion

A DISSECTION game similar to TANGRAMS described in fragmentary manuscripts attributed to Archimedes and was referred to as the LOCULUS OF ARCHIMEDES (Archimedes' box) in Latin texts. The word Stomachion has as its root the Greek word for stomach. The game consisted of 14 flat pieces of various shapes arranged in the shape of a square. Like TANGRAMS, the object is to rearrange the pieces to form interesting shapes.

## Størmer Number

A Størmer number is a POSITIVE INTEGER  $n$  for which the largest PRIME factor  $p$  of  $n^2 + 1$  is at least  $2n$ . Every GREGORY NUMBER  $t_x$  can be expressed uniquely as a sum of  $t_n$ s where the  $n$ s are Størmer numbers. Conway and Guy (1996) give a table of Størmer numbers reproduced below (Sloane's A005529). In a paper on INVERSE TANGENT relations, Todd (1949) gives a similar compilation.

$n$	$p$	$n$	$p$	$n$	$p$	$n$	$p$	$n$	$p$
1	2	10	101	19	181	26	617	35	613
2	5	11	61	20	401	27	73	36	1297
4	17	12	29	22	97	28	157	37	137
5	13	14	197	23	53	29	421	39	761
6	37	15	113	24	577	33	109	40	1601
9	41	16	257	25	313	34	89	42	353

### Strange Loop

A phenomenon in which, whenever movement is made upwards or downwards through the levels of some heirarchical system, the system unexpectedly arrives back where it started. Hofstadter (1987) uses the strange loop as a paradigm in which to interpret paradoxes in logic (such as GRELLING'S PARADOX and RUSSELL'S PARADOX) and calls a system in which a strange loop appears a TANGLED HIERARCHY.

see also GRELLING'S PARADOX, RUSSELL'S PARADOX, TANGLED HIERARCHY

### Strassen Formulas

The usual number of scalar operations (i.e., the total number of additions and multiplications) required to perform  $n \times n$  MATRIX MULTIPLICATION is

$$M(n) = 2n^3 - n^2 \quad (1)$$

(i.e.,  $n^3$  multiplications and  $n^3 - n^2$  additions). However, Strassen (1969) discovered how to multiply two MATRICES in

$$S(n) = 7 \cdot 7^{\lg n} - 6 \cdot 4^{\lg n} \quad (2)$$

scalar operations, where  $\lg$  is the LOGARITHM to base 2, which is less than  $M(n)$  for  $n > 654$ . For  $n$  a power of two ( $n = 2^k$ ), the two parts of (2) can be written

$$7 \cdot 7^{\lg n} = 7 \cdot 7^{\lg 2^k} = 7 \cdot 7^k = 7 \cdot 2^{k \lg 7} = 7(2^k)^{\lg 7} = 7n^{\lg 7} \quad (3)$$

$$6 \cdot 4^{\lg n} = 6 \cdot 4^{\lg 2^k} = 6 \cdot 4^{k \lg 2} = 6 \cdot 4^k = 6(2^k)^2 = 6n^2, \quad (4)$$

so (2) becomes

$$S(2^k) = 7n^{\lg 7} - 6n^2. \quad (5)$$

Two  $2 \times 2$  matrices can therefore be multiplied

$$C = AB \quad (6)$$

$$\begin{bmatrix} c_{11} & c_{12} \\ c_{21} & c_{22} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} \quad (7)$$

with only

$$S(2) = 7 \cdot 2^{\lg 7} - 6 \cdot 2^2 = 49 - 24 = 25 \quad (8)$$

scalar operations (as it turns out, seven of them are multiplications and 18 are additions). Define the seven products (involving a total of 10 additions) as

$$Q_1 \equiv (a_{11} + a_{22})(b_{11} + b_{22}) \quad (9)$$

$$Q_2 \equiv (a_{21} + a_{22})b_{11} \quad (10)$$

$$Q_3 \equiv a_{11}(b_{12} - b_{22}) \quad (11)$$

$$Q_4 \equiv a_{22}(-b_{11} + b_{21}) \quad (12)$$

$$Q_5 \equiv (a_{11} + a_{12})b_{22} \quad (13)$$

$$Q_6 \equiv (-a_{11} + a_{12})(b_{11} + b_{12}) \quad (14)$$

$$Q_7 \equiv (a_{12} - a_{22})(b_{21} + b_{22}). \quad (15)$$

Then the matrix product is given using the remaining eight additions as

$$c_{11} = Q_1 + Q_4 - Q_5 + Q_7 \quad (16)$$

$$c_{21} = Q_2 + Q_4 \quad (17)$$

$$c_{12} = Q_3 + Q_5 \quad (18)$$

$$c_{22} = Q_1 + Q_3 - Q_2 + Q_6 \quad (19)$$

(Strassen 1969, Press *et al.* 1989).

Matrix inversion of a  $2 \times 2$  matrix  $A$  to yield  $C = A^{-1}$  can also be done in fewer operations than expected using the formulas

$$R_1 \equiv a_{11}^{-1} \quad (20)$$

$$R_2 \equiv a_{21}R_1 \quad (21)$$

$$R_3 \equiv R_1a_{12} \quad (22)$$

$$R_4 \equiv a_{21}R_3 \quad (23)$$

$$R_5 \equiv R_4 - a_{22} \quad (24)$$

$$R_6 \equiv R_5^{-1} \quad (25)$$

$$c_{12} = R_3R_6 \quad (26)$$

$$c_{21} = R_6R_2 \quad (27)$$

$$R_7 = R_3c_{21} \quad (28)$$

$$c_{11} = R_1 - R_7 \quad (29)$$

$$c_{22} = -R_6 \quad (30)$$

(Strassen 1969, Press *et al.* 1989). The leading exponent for Strassen's algorithm for a POWER of 2 is  $\lg 7 \approx 2.808$ . The best leading exponent currently known is 2.376 (Coppersmith and Winograd 1990). It has been shown that the exponent must be at least 2.

The sum identity

$$\sum_{j=0}^{\infty} \binom{n}{j}^3 = \sum_{k=0}^{\infty} \binom{n}{k}^2 \binom{2(n-k)}{n},$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT.

see also BINOMIAL COEFFICIENT

**Striction Curve**

A NONCYLINDRICAL RULED SURFACE always has a parameterization of the form

$$\mathbf{x}(u, v) = \boldsymbol{\sigma}(u) + v\boldsymbol{\delta}(u), \quad (1)$$

where  $|\boldsymbol{\delta}| = 1$ ,  $\boldsymbol{\sigma}' \cdot \boldsymbol{\delta}' = 0$ , and  $\boldsymbol{\sigma}$  is called the striction curve of  $\mathbf{x}$ . Furthermore, the striction curve does not depend on the choice of the base curve. The striction and DIRECTOR CURVES of the HELICOID

$$\mathbf{x}(u, v) = \begin{bmatrix} 0 \\ 0 \\ bu \end{bmatrix} + av \begin{bmatrix} \cos u \\ \sin u \\ 0 \end{bmatrix} \quad (2)$$

are

$$\boldsymbol{\sigma}(u) = \begin{bmatrix} 0 \\ 0 \\ bu \end{bmatrix} \quad (3)$$

$$\boldsymbol{\delta}(u) = \begin{bmatrix} a \cos u \\ a \sin u \\ 0 \end{bmatrix}. \quad (4)$$

For the HYPERBOLIC PARABOLOID

$$\mathbf{x}(u, v) = \begin{bmatrix} u \\ 0 \\ 0 \end{bmatrix} + v \begin{bmatrix} 0 \\ 1 \\ u \end{bmatrix}, \quad (5)$$

the striction and DIRECTOR CURVES are

$$\boldsymbol{\sigma}(u) = \begin{bmatrix} u \\ 0 \\ 0 \end{bmatrix} \quad (6)$$

$$\boldsymbol{\delta}(u) = \begin{bmatrix} 0 \\ 1 \\ u \end{bmatrix}. \quad (7)$$

**Strip**

see CRITICAL STRIP, MÖBIUS STRIP

**Strong Convergence**

Strong convergence is the type of convergence usually associated with convergence of a SEQUENCE. More formally, a SEQUENCE  $\{x_n\}$  of VECTORS in an INNER PRODUCT SPACE  $E$  is called convergent to a VECTOR  $x$  in  $E$  if

$$\|x_n - x\| \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

see also CONVERGENT SEQUENCE, INNER PRODUCT SPACE, WEAK CONVERGENCE

**Strong Elliptic Pseudoprime**

Let  $n$  be an ELLIPTIC PSEUDOPRIME associated with  $(E, P)$ , and let  $n+1 = 2^s k$  with  $k$  ODD and  $s \geq 0$ . Then  $n$  is a strong elliptic pseudoprime when either  $kP \equiv 0 \pmod{n}$  or  $2^r kP \equiv 0 \pmod{n}$  for some  $r$  with  $1 \leq r < s$ .

see also ELLIPTIC PSEUDOPRIME

**References**

Ribenboim, P. *The New Book of Prime Number Records*, 3rd ed. New York: Springer-Verlag, pp. 132–134, 1996.

**Strong Frobenius Pseudoprime**

A PSEUDOPRIME which obeys an additional restriction beyond that required for a FROBENIUS PSEUDOPRIME. A number  $n$  with  $(n, 2a) = 1$  is a strong Frobenius pseudoprime with respect to  $x - a$  IFF  $n$  is a STRONG PSEUDOPRIME with respect to  $f(x)$ . Every strong Frobenius pseudoprime with respect to  $x - a$  is an EULER PSEUDOPRIME to the base  $a$ .

Every strong Frobenius pseudoprime with respect to  $f(x) = x^2 - bx - c$  such that  $((b^2 + 4c)/n) = -1$  is a STRONG LUCAS PSEUDOPRIME with parameters  $(b, c)$ . Every strong Frobenius pseudoprime  $n$  with respect to  $x^2 - bx + 1$  is an EXTRA STRONG LUCAS PSEUDOPRIME to the base  $b$ .

see also FROBENIUS PSEUDOPRIME

**Strong Lucas Pseudoprime**

Let  $U(P, Q)$  and  $V(P, Q)$  be LUCAS SEQUENCES generated by  $P$  and  $Q$ , and define

$$D \equiv P^2 - 4Q.$$

Let  $n$  be an ODD COMPOSITE NUMBER with  $(n, D) = 1$ , and  $n - (D/n) = 2^s d$  with  $d$  ODD and  $s \geq 0$ , where  $(a/b)$  is the LEGENDRE SYMBOL. If

$$U_d \equiv 0 \pmod{n}$$

or

$$V_{2^r d} \equiv 0 \pmod{n}$$

for some  $r$  with  $0 \leq r < s$ , then  $n$  is called a strong Lucas pseudoprime with parameters  $(P, Q)$ .

A strong Lucas pseudoprime is a LUCAS PSEUDOPRIME to the same base. Arnault (1997) showed that any COMPOSITE NUMBER  $n$  is a strong Lucas pseudoprime for at most 4/15 of possible bases (unless  $n$  is the PRODUCT OF TWIN PRIMES having certain properties).

see also EXTRA STRONG LUCAS PSEUDOPRIME, LUCAS PSEUDOPRIME

**References**

Arnault, F. "The Rabin-Monier Theorem for Lucas Pseudoprimes." *Math. Comput.* **66**, 869–881, 1997.

**Strong Pseudoprime**

A strong pseudoprime to a base  $a$  is an ODD COMPOSITE NUMBER  $n$  with  $n - 1 = d \cdot 2^s$  (for  $d$  ODD) for which either

$$a^d \equiv 1 \pmod{n} \tag{1}$$

or

$$a^{d \cdot 2^r} \equiv -1 \pmod{n} \tag{2}$$

for some  $r \in [0, s)$ .

The definition is motivated by the fact that a FERMAT PSEUDOPRIME  $n$  to the base  $b$  satisfies

$$b^{n-1} - 1 \equiv 0 \pmod{n}. \tag{3}$$

But since  $n$  is ODD, it can be written  $n = 2m + 1$ , and

$$b^{2m} - 1 = (b^m - 1)(b^m + 1) \equiv 0 \pmod{n}. \tag{4}$$

If  $n$  is PRIME, it must DIVIDE at least one of the FACTORS, but can't DIVIDE both because it would then DIVIDE their difference

$$(b^m + 1) - (b^m - 1) = 2. \quad (5)$$

Therefore,

$$b^m \equiv \pm 1 \pmod{n}, \quad (6)$$

so write  $n = 2^a t + 1$  to obtain

$$b^{n-1} - 1 = (b^t - 1)(b^t + 1)(b^{2t} + 1) \cdots (b^{2^{a-1}t} + 1). \quad (7)$$

If  $n$  DIVIDES exactly one of these FACTORS but is COMPOSITE, it is a strong pseudoprime. A COMPOSITE number is a strong pseudoprime to at most  $1/4$  of all bases less than itself (Monier 1980, Rabin 1980). The strong pseudoprimes provide the basis for MILLER'S PRIMALITY TEST and RABIN-MILLER STRONG PSEUDOPRIME TEST.

A strong pseudoprime to the base  $a$  is also an EULER PSEUDOPRIME to the base  $a$  (Pomerance *et al.* 1980). The strong pseudoprimes include some EULER PSEUDOPRIMES, FERMAT PSEUDOPRIMES, and CARMICHAEL NUMBERS.

There are 4842 strong psp(2) less than  $2.5 \times 10^{10}$ , where a psp(2) is also known as a POULET NUMBER. The strong  $k$ -pseudoprime test for  $k = 2, 3, 5$  correctly identifies all PRIMES below  $2.5 \times 10^{10}$  with only 13 exceptions, and if 7 is added, then the only exception less than  $2.5 \times 10^{10}$  is 315031751. Jaeschke (1993) showed that there are only 101 strong pseudoprimes for the bases 2, 3, and 5 less than  $10^{12}$ , nine if 7 is added, and none if 11 is added. Also, the bases 2, 13, 23, and 1662803 have no exceptions up to  $10^{12}$ .

If  $n$  is COMPOSITE, then there is a base for which  $n$  is not a strong pseudoprime. There are therefore no "strong CARMICHAEL NUMBERS." Let  $\psi_k$  denote the smallest strong pseudoprime to all of the first  $k$  PRIMES taken as bases (i.e, the smallest ODD NUMBER for which the RABIN-MILLER STRONG PSEUDOPRIME TEST on bases less than or equal to  $k$  fails). Jaeschke (1993) computed  $\psi_k$  from  $k = 5$  to 8 and gave upper bounds for  $k = 9$  to 11.

$$\psi_1 = 2047$$

$$\psi_2 = 1373653$$

$$\psi_3 = 25326001$$

$$\psi_4 = 3215031751$$

$$\psi_5 = 2152302898747$$

$$\psi_6 = 3474749660383$$

$$\psi_7 = 34155071728321$$

$$\psi_8 = 34155071728321$$

$$\psi_9 \leq 41234316135705689041$$

$$\psi_{10} \leq 1553360566073143205541002401$$

$$\psi_{11} \leq 56897193526942024370326972321$$

(Sloane's A014233). A seven-step test utilizing these results (Riesel 1994) allows all numbers less than  $3.4 \times 10^{14}$  to be tested.

Pomerance *et al.* (1980) have proposed a test based on a combination of STRONG PSEUDOPRIMES and LUCAS PSEUDOPRIMES. They offer a \$620 reward for discovery of a COMPOSITE NUMBER which passes their test (Guy 1994, p. 28).

see TRIPLE-FREE SET

**Strophoid**

Let  $C$  be a curve, let  $O$  be a fixed point (the POLE), and let  $O'$  be a second fixed point. Let  $P$  and  $P'$  be points on a line through  $O$  meeting  $C$  at  $Q$  such that  $P'Q = QP = QO'$ . The LOCUS of  $P$  and  $P'$  is called the strophoid of  $C$  with respect to the POLE  $O$  and fixed point  $O'$ . Let  $C$  be represented parametrically by  $(f(t), g(t))$ , and let  $O = (x_0, y_0)$  and  $O' = (x_1, y_1)$ . Then the equation of the strophoid is

$$x = f \pm \sqrt{\frac{(x_1 - f)^2 + (y_1 - g)^2}{1 + m^2}} \quad (1)$$

$$y = g \pm \sqrt{\frac{(x_1 - f)^2 + (y_1 - g)^2}{1 + m^2}}, \quad (2)$$

where

$$m \equiv \frac{g - y_0}{f - x_0}. \quad (3)$$

The name strophoid means "belt with a twist," and was proposed by Montucci in 1846 (MacTutor Archive). The polar form for a general strophoid is

$$r = \frac{b \sin(a - 2\theta)}{\sin(a - \theta)}. \quad (4)$$

If  $a = \pi/2$ , the curve is a RIGHT STROPHOID. The following table gives the strophoids of some common curves.

Curve	Pole	Fixed Point	Strophoid
line	not on line	on line	oblique strophoid
line	not on line	foot of $\perp$	right strophoid
		origin to line	
circle	center	on circumf.	Freeth's nephroid

see also RIGHT STROPHOID

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, pp. 496, 1972.

#### Struve Function

Abramowitz and Stegun (1972, pp. 496–499) define the Struve function as

$$\mathcal{H}_\nu(z) = \left(\frac{1}{2}z\right)^{\nu+1} \sum_{k=0}^{\infty} \frac{(-1)^k \left(\frac{1}{2}z\right)^{2k}}{\Gamma(k + \frac{3}{2})\Gamma(k + \nu + \frac{3}{2})}, \quad (1)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION. Watson (1966, p. 338) defines the Struve function as

$$\mathcal{H}_\nu(z) \equiv \frac{2\left(\frac{1}{2}z\right)^\nu}{\Gamma(\nu + \frac{1}{2})\Gamma(\frac{1}{2})} \int_0^1 (1-t^2)^{\nu-1/2} \sin(zt) dt. \quad (2)$$

The series expansion is

$$\mathcal{H}_\nu(z) = \sum_{m=0}^{\infty} (-1)^m \frac{\left(\frac{1}{2}z\right)^{2m+\nu+1}}{\Gamma(m + \frac{3}{2})\Gamma(\nu + m + \frac{3}{2})}. \quad (3)$$

For half integral orders,

$$\begin{aligned} \mathcal{H}_{n+1/2}(z) &= Y_{n+1/2}(z) + \frac{1}{\pi} \sum_{m=0}^n \frac{\Gamma(m + \frac{1}{2})\left(\frac{1}{2}z\right)^{-2m+n-1/2}}{\Gamma(n+1-m)} \\ \mathcal{H}_{-(n+1/2)}(z) &= (-1)^n J_{n+1/2}(z). \end{aligned} \quad (4)$$

The Struve function and its derivatives satisfy

$$\mathcal{H}_{\nu-1}(z) - \mathcal{H}_{\nu+1}(z) = 2\mathcal{H}'_\nu(z) - \frac{\left(\frac{1}{2}z\right)^\nu}{\sqrt{\pi}\Gamma(\nu + \frac{3}{2})}. \quad (6)$$

#### Student's *t*-Distribution

A DISTRIBUTION published by William Gosset in 1908. His employer, Guinness Breweries, required him to publish under a pseudonym, so he chose "Student." Given  $n$  independent measurements  $x_i$ , let

$$t \equiv \frac{\bar{x} - \mu}{s/\sqrt{n}}, \quad (1)$$

where  $\mu$  is the population MEAN,  $\bar{x}$  is the sample MEAN, and  $s$  is the ESTIMATOR for population STANDARD DEVIATION (i.e., the SAMPLE VARIANCE) defined by

$$s^2 \equiv \frac{1}{N-1} \sum_{i=1}^n (x_i - \bar{x})^2. \quad (2)$$

Student's *t*-distribution is defined as the distribution of the random variable  $t$  which is (very loosely) the "best" that we can do not knowing  $\sigma$ . If  $\sigma = s$ ,  $t = z$  and the distribution becomes the NORMAL DISTRIBUTION. As  $N$  increases, Student's *t*-distribution approaches the NORMAL DISTRIBUTION.

Student's *t*-distribution is arrived at by transforming to STUDENT'S *z*-DISTRIBUTION with

$$z \equiv \frac{\bar{x} - \mu}{s}. \quad (3)$$

Then define

$$t \equiv z\sqrt{n-1}. \quad (4)$$

The resulting probability and cumulative distribution functions are

$$\begin{aligned} f_r(t) &= \frac{\Gamma\left(\frac{r+1}{2}\right)}{\sqrt{r\pi} \Gamma\left(\frac{r}{2}\right) \left(1 + \frac{t^2}{r}\right)^{(r+1)/2}} \\ &= \frac{\left(\frac{r}{r+t^2}\right)^{(1+r)/2}}{\sqrt{r} B\left(\frac{1}{2}r, \frac{1}{2}\right)} \\ F_r(t) &= \int_{-\infty}^t \frac{\Gamma\left(\frac{r+1}{2}\right)}{\sqrt{r\pi} \Gamma\left(\frac{r}{2}\right) \left(1 + \frac{t^2}{r}\right)^{(r+1)/2}} dt \\ &= \frac{1}{\sqrt{n} B\left(\frac{r}{2}, \frac{1}{2}\right) \left(1 + \frac{t^2}{r}\right)^{(r+1)/2}} \\ &= \frac{1}{2} + \frac{1}{2} \left[ I\left(1; \frac{1}{2}n, \frac{1}{2}\right) - I\left(\frac{r}{r+t^2}, \frac{1}{2}n, \frac{1}{2}\right) \right], \end{aligned} \quad (5)$$

where

$$r \equiv n-1 \quad (7)$$

is the number of DEGREES OF FREEDOM,  $-\infty < t < \infty$ ,  $\Gamma(z)$  is the GAMMA FUNCTION,  $B(a, b)$  is the BETA FUNCTION, and  $I(z; a, b)$  is the REGULARIZED BETA FUNCTION defined by

$$I(z; a, b) = \frac{B(z; a, b)}{B(a, b)}. \quad (8)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS of Student's *t*-distribution are

$$\mu = 0 \quad (9)$$

$$\sigma^2 = \frac{r}{r-2} \quad (10)$$

$$\gamma_1 = 0 \quad (11)$$

$$\gamma_2 = \frac{6}{r-4}. \quad (12)$$

Beyer (1987, p. 514) gives 60%, 70%, 90%, 95%, 97.5%, 99%, 99.5%, and 99.95% confidence intervals, and Goulden (1956) gives 50%, 90%, 95%, 98%, 99%, and 99.9% confidence intervals. A partial table is given below for small  $r$  and several common confidence intervals.

$r$	80%	90%	95%	99%
1	3.08	6.31	12.71	63.66
2	1.89	2.92	4.30	9.92
3	1.64	2.35	3.18	5.84
4	1.53	2.13	2.78	4.60
5	1.48	2.01	2.57	4.03
10	1.37	1.81	2.23	4.14
30	1.31	1.70	2.04	2.75
100	1.29	1.66	1.98	2.63
$\infty$	1.28	1.65	1.96	2.58

The so-called  $A(t|n)$  distribution is useful for testing if two observed distributions have the same MEAN.  $A(t|n)$  gives the probability that the difference in two observed MEANS for a certain statistic  $t$  with  $n$  DEGREES OF FREEDOM would be smaller than the observed value purely by chance:

$$A(t|n) = \frac{1}{\sqrt{n} B(\frac{1}{2}, \frac{1}{2}n)} \int_{-t}^t \left(1 + \frac{x^2}{n}\right)^{-(1+n)/2} dx. \quad (13)$$

Let  $X$  be a NORMALLY DISTRIBUTED random variable with MEAN 0 and VARIANCE  $\sigma^2$ , let  $Y^2/\sigma^2$  have a CHI-SQUARED DISTRIBUTION with  $n$  DEGREES OF FREEDOM, and let  $X$  and  $Y$  be independent. Then

$$t \equiv \frac{X\sqrt{n}}{Y} \quad (14)$$

is distributed as Student's *t* with  $n$  DEGREES OF FREEDOM.

The noncentral Student's *t*-distribution is given by

$$P(x) = \frac{n^{n/2} n!}{2^n e^{\lambda^2/2} \Gamma(\frac{1}{2}n)} \times \left\{ \frac{\sqrt{2} \lambda x (n + x^2)^{-(1+n/2)} {}_1F_1\left(1 + \frac{1}{2}n; \frac{3}{2}; \frac{\lambda^2 x^2}{2(n+x^2)}\right)}{\Gamma(\frac{1}{2}(1+n))} + \frac{e^{(\lambda^2 x^2)/(2(n+x^2))} \sqrt{\pi} (n + x^2)^{-(n+1)/2} L_{n/2}^{-1/2}\left(-\frac{\lambda^2 x^2}{2(n+x^2)}\right)}{\Gamma(\frac{1}{2}(1+n))} \right\}, \quad (15)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION,  ${}_1F_1(a; b; z)$  is a CONFLUENT HYPERGEOMETRIC FUNCTION, and  $L_n^m(x)$  is an associated LAGUERRE POLYNOMIAL.

### Student's *z*-Distribution

The probability density function and cumulative distribution functions for Student's *z*-distribution are given by

$$f(z) = \frac{\Gamma(\frac{n}{2})}{\sqrt{\pi} \Gamma(\frac{n-1}{2})} (1 + z^2)^{-n/2} \quad (1)$$

$$D(z) = \frac{-z^{1-n} \Gamma(\frac{1}{2}n) {}_2F_1(\frac{1}{2}(n-1), \frac{1}{2}n; \frac{1}{2}(n+1); -z^{-2})}{2\sqrt{\pi} \Gamma(\frac{1}{2}(n+1))}. \quad (2)$$

The MEAN is 0, so the MOMENTS are

$$\mu_1 = 0 \quad (3)$$

$$\mu_2 = \frac{1}{n-3} \quad (4)$$

$$\mu_3 = 0 \quad (5)$$

$$\mu_4 = \frac{3}{(n-3)(n-5)}. \quad (6)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = 0 \quad (7)$$

$$\sigma^2 = \frac{1}{n-3} \quad (8)$$

$$\gamma_1 = 0 \quad (9)$$

$$\gamma_2 = \frac{6}{n-5}. \quad (10)$$

Letting

$$z \equiv \frac{(\bar{x} - \mu)}{s}, \quad (11)$$

where  $x$  is the sample MEAN and  $\mu$  is the population MEAN gives STUDENT'S  $t$ -DISTRIBUTION.

see also STUDENT'S  $t$ -DISTRIBUTION

### Study's Theorem

Given three curves  $\phi_1, \phi_2, \phi_3$  with the common group of ordinary points  $G$  (which may be empty), let their remaining groups of intersections  $g_{23}, g_{31}$ , and  $g_{12}$  also be ordinary points. If  $\phi'_1$  is any other curve through  $g_{23}$ , then there exist two other curves  $\phi'_2, \phi'_3$  such that the three combined curves  $\phi_i \phi'_i$  are of the same order and LINEARLY DEPENDENT, each curve  $\phi'_k$  contains the corresponding group  $g_{ij}$ , and every intersection of  $\phi_i$  or  $\phi'_i$  with  $\phi_j$  or  $\phi'_j$  lies on  $\phi_k$  or  $\phi'_k$ .

### Sturm Chain

The series of STURM FUNCTIONS arising in application of the STURM THEOREM.

see also STURM FUNCTION, STURM THEOREM

### Sturm Function

Given a function  $f(x) \equiv f_0(x)$ , write  $f_1 \equiv f'(x)$  and define the Sturm functions by

$$f_n(x) = - \left\{ f_{n-2}(x) - f_{n-1}(x) \left[ \frac{f_{n-2}(x)}{f_{n-1}(x)} \right] \right\}, \quad (1)$$

where  $[P(x)/Q(x)]$  is a polynomial quotient. Then construct the following chain of Sturm functions,

$$\begin{aligned} f_0 &= q_0 f_1 - f_2 \\ f_1 &= q_1 f_2 - f_3 \\ f_2 &= q_2 f_3 - f_4 \\ &\vdots \\ f_{s-2} &= q_{s-2} f_{s-1} - f_s, \end{aligned} \quad (2)$$

known as a STURM CHAIN. The chain is terminated when a constant  $-f_s(x)$  is obtained.

Sturm functions provide a convenient way for finding the number of real roots of an algebraic equation with

real coefficients over a given interval. Specifically, the difference in the number of sign changes between the Sturm functions evaluated at two points  $x = a$  and  $x = b$  gives the number of real roots in the interval  $(a, b)$ . This powerful result is known as the STURM THEOREM.

As a specific application of Sturm functions toward finding POLYNOMIAL ROOTS, consider the function  $f_0(x) = x^5 - 3x - 1$ , plotted above, which has roots  $-1.21465$ ,  $-0.334734$ ,  $0.0802951 \pm 1.32836i$ , and  $1.38879$  (three of which are real). The DERIVATIVE is given by  $f'(x) = 5x^4 - 3$ , and the STURM CHAIN is then given by

$$f_0 = x^5 - 3x - 1 \quad (3)$$

$$f_1 = 5x^4 - 3 \quad (4)$$

$$f_2 = \frac{1}{5}(12x + 5) \quad (5)$$

$$f_3 = \frac{59083}{20736}. \quad (6)$$

The following table shows the signs of  $f_i$  and the number of sign changes  $\Delta$  obtained for points separated by  $\Delta x = 2$ .

$x$	$f_0$	$f_1$	$f_2$	$f_3$	$\Delta$
-2	-1	1	-1	1	3
0	-1	-1	1	1	1
2	1	1	1	1	0

This shows that  $3 - 1 = 2$  real roots lie in  $(-2, 0)$ , and  $1 - 0 = 1$  real root lies in  $(0, 2)$ . Reducing the spacing to  $\Delta x = 0.5$  gives the following table.

$x$	$f_0$	$f_1$	$f_2$	$f_3$	$\Delta$
-2.0	-1	1	-1	1	3
-1.5	-1	1	-1	1	3
-1.0	1	1	-1	1	2
-0.5	1	-1	-1	1	2
0.0	-1	-1	1	1	1
0.5	-1	-1	1	1	1
1.0	-1	1	1	1	1
1.5	1	1	1	1	0
2.0	1	1	1	1	0

This table isolates the three real roots and shows that they lie in the intervals  $(-1.5, -1.0)$ ,  $(-0.5, 0.0)$ , and  $(1.0, 1.5)$ . If desired, the intervals in which the roots fall could be further reduced.

The Sturm functions satisfy the following conditions:

1. Two neighboring functions do not vanish simultaneously at any point in the interval.
2. At a null point of a Sturm function, its two neighboring functions are of different signs.
3. Within a sufficiently small AREA surrounding a zero point of  $f_0(x)$ ,  $f_1(x)$  is everywhere greater than zero or everywhere smaller than zero.

### Sturm-Liouville Equation

A second-order ORDINARY DIFFERENTIAL EQUATION

$$\frac{d}{dx} \left[ p(x) \frac{dy}{dx} \right] + [\lambda w(x) - q(x)]y = 0,$$

where  $\lambda$  is a constant and  $w(x)$  is a known function called either the density or WEIGHTING FUNCTION. The solutions (with appropriate boundary conditions) of  $\lambda$  are called EIGENVALUES and the corresponding  $u_\lambda(x)$  EIGENFUNCTIONS. The solutions of this equation satisfy important mathematical properties under appropriate boundary conditions (Arfken 1985).

### Sturmian Separation Theorem

Let  $A_r = a_{ij}$  be a SEQUENCE of  $N$  SYMMETRIC MATRICES of increasing order with  $i, j = 1, 2, \dots, r$  and  $r = 1, 2, \dots, N$ . Let  $\lambda_k(A_r)$  be the  $k$ th EIGENVALUE of  $A_r$  for  $k = 1, 2, \dots, r$ , where the ordering is given by

$$\lambda_1(A_r) \geq \lambda_2(A_r) \geq \dots \geq \lambda_r(A_r).$$

Then it follows that

$$\lambda_{k+1}(A_{i+1}) \leq \lambda_k(A_i) \leq \lambda_k(A_{i+1}).$$

### Sturmian Sequence

If a SEQUENCE has the property that the BLOCK GROWTH function  $B(n) = n + 1$  for all  $n$ , then it is said to have minimal block growth, and the sequence is called a Sturmian sequence. An example of this is the sequence arising from the SUBSTITUTION MAP

$$\begin{aligned} 0 &\rightarrow 01 \\ 1 &\rightarrow 0, \end{aligned}$$

yielding  $0 \rightarrow 01 \rightarrow 010 \rightarrow 01001 \rightarrow 01001010 \rightarrow \dots$ , which gives us the Sturmian sequence 01001010...

STURM FUNCTIONS are sometimes also said to form a Sturmian sequence.

see also STURM FUNCTION, STURM THEOREM

### Subalgebra

An ALGEBRA  $S'$  which is part of a large ALGEBRA  $S$  and shares its properties.

see also ALGEBRA

### Subanalytic

$X \subseteq \mathbb{R}^n$  is subanalytic if, for all  $x \in \mathbb{R}^n$ , there is an open  $U$  and  $Y \subset \mathbb{R}^{n+m}$  a bounded SEMIANALYTIC set such that  $X \cap U$  is the projection of  $Y$  into  $U$ .

see also SEMIANALYTIC

#### References

### Subfactorial

The number of PERMUTATIONS of  $n$  objects in which no object appear in its natural place (i.e., so-called “DERANGEMENTS”).

$$!n \equiv n! \sum_{k=0}^n \frac{(-1)^k}{k!} \quad (1)$$

or

$$!n \equiv \left[ \frac{n!}{e} \right], \quad (2)$$

where  $k!$  is the usual FACTORIAL and  $[x]$  is the NINT function. The first few values are  $!1 = 0$ ,  $!2 = 1$ ,  $!3 = 2$ ,  $!4 = 9$ ,  $!5 = 44$ ,  $!6 = 265$ ,  $!7 = 1854$ ,  $!8 = 14833$ , ... (Sloane's A000166). For example, the only DERANGEMENTS of  $\{1, 2, 3\}$  are  $\{2, 3, 1\}$  and  $\{3, 1, 2\}$ , so  $!3 = 2$ . Similarly, the DERANGEMENTS of  $\{1, 2, 3, 4\}$  are  $\{2, 1, 4, 3\}$ ,  $\{2, 3, 4, 1\}$ ,  $\{2, 4, 1, 3\}$ ,  $\{3, 1, 4, 2\}$ ,  $\{3, 4, 1, 2\}$ ,  $\{3, 4, 2, 1\}$ ,  $\{4, 1, 2, 3\}$ ,  $\{4, 3, 1, 2\}$ , and  $\{4, 3, 2, 1\}$ , so  $!4 = 9$ .

The subfactorials are also called the RENCONTRES NUMBERS and satisfy the RECURRENCE RELATIONS

$$!n = n \cdot !(n-1) + (-1)^n \quad (3)$$

$$!(n+1) = n[!n + !(n-1)]. \quad (4)$$

The subfactorial can be considered a special case of a restricted ROOKS PROBLEM.

The only number equal to the sum of subfactorials of its digits is

$$148,349 = !1 + !4 + !8 + !3 + !4 + !9 \quad (5)$$

(Madachy 1979).

see also DERANGEMENT, FACTORIAL, MARRIED COUPLES PROBLEM, ROOKS PROBLEM, SUPERFACTORIAL

### Subfield

If a subset  $S$  of the elements of a FIELD  $F$  satisfies the FIELD AXIOMS with the same operations of  $F$ , then  $S$  is called a subfield of  $F$ . Let  $F$  be a FINITE FIELD of order  $p^n$ , then there exists a subfield of ORDER  $p^m$  for PRIME  $p$  IFF  $m$  DIVIDES  $n$ .

see also FIELD, SUBMANIFOLD, SUBSPACE

### Subgraph

A GRAPH  $G'$  whose VERTICES and EDGES form subsets of the VERTICES and EDGES of a given GRAPH  $G$ . If  $G'$  is a subgraph of  $G$ , then  $G$  is said to be a SUPERGRAPH of  $G'$ .

see also GRAPH (GRAPH THEORY), SUPERGRAPH

### Subgroup

A subset of GROUP elements which satisfies the four GROUP requirements. The ORDER of any subgroup of a GROUP ORDER  $h$  must be a DIVISOR of  $h$ .

see also CARTAN SUBGROUP, COMPOSITION SERIES, FITTING SUBGROUP, GROUP

### Sublime Number

Let  $\tau(n)$  and  $\sigma(n)$  denote the number and sum of the divisors of  $n$ , respectively (i.e., the zeroth- and first-order DIVISOR FUNCTIONS). A number  $N$  is called sublime if  $\tau(N)$  and  $\sigma(N)$  are both PERFECT NUMBERS. The only two known sublime numbers are 12 and

$$60865556702383789896703717342431696 \dots \\ \dots 22657830773351885970528324860512791691264.$$

It is not known if any ODD sublime number exists.

see also DIVISOR FUNCTION, PERFECT NUMBER

### Submanifold

A  $C^\infty$  (infinitely differentiable) MANIFOLD is said to be a submanifold of a  $C^\infty$  MANIFOLD  $M'$  if  $M$  is a SUBSET of  $M'$  and the IDENTITY MAP of  $M$  into  $M'$  is an embedding.

see also MANIFOLD, SUBFIELD, SUBSPACE

### Submatrix

An  $p \times q$  submatrix of an  $m \times n$  MATRIX (with  $p \leq m$ ,  $n \leq q$ ) is a  $p \times q$  MATRIX formed by taking a block of the entries of this size from the original matrix.

see also MATRIX

### Subnormal

$L$  is a subnormal SUBGROUP of  $H$  if there is a “normal series” (in the sense of Jordan-Holder) from  $L$  to  $H$ .

### Subordinate Norm

see NATURAL NORM

### Subscript

A quantity displayed below the normal line of text (and generally in a smaller point size), as the “ $i$ ” in  $a_i$ , is called a subscript. Subscripts are commonly used to indicate indices ( $a_{ij}$  is the entry in the  $i$ th row and  $j$ th column of a MATRIX  $A$ ), partial differentiation ( $y_x$  is an abbreviation for  $\partial y / \partial x$ ), and a host of other operations and notations in mathematics.

see also SUPERScript

**Subsequence**

A subsequence of a SEQUENCE  $S = \{x_i\}_{i=1}^n$  is a derived sequence  $\{y_i\}_{i=1}^N = \{x_{i+j}\}$  for some  $j \geq 0$  and  $N \leq n - j$ . More generally, the word subsequence is sometimes used to mean a sequence derived from a sequence  $S$  by discarding some of its terms.

see also LOWER-TRIMMED SUBSEQUENCE, UPPER-TRIMMED SUBSEQUENCE

**Subset**

A portion of a SET.  $B$  is a subset of  $A$  (written  $B \subseteq A$ ) IFF every member of  $B$  is a member of  $A$ . If  $B$  is a PROPER SUBSET of  $A$  (i.e., a subset other than the set itself), this is written  $B \subset A$ .

A SET of  $n$  elements has  $2^n$  subsets (including the set itself and the EMPTY SET). For sets of  $n = 1, 2, \dots$  elements, the numbers of subsets are therefore 2, 4, 8, 16, 32, 64, ... (Sloane's A000079). For example, the set  $\{1\}$  has the two subsets  $\emptyset$  and  $\{1\}$ . Similarly, the set  $\{1, 2\}$  has subsets  $\emptyset$  (the EMPTY SET,  $\{1\}$ ,  $\{2\}$ , and  $\{1, 2\}$ .

see also EMPTY SET, IMPLIES,  $k$ -SUBSET, PROPER SUBSET, SUPERSET, VENN DIAGRAM

**Subspace**

Let  $V$  be a REAL VECTOR SPACE (e.g., the real continuous functions  $C(I)$  on a CLOSED INTERVAL  $I$ , 2-D EUCLIDEAN SPACE  $\mathbb{R}^2$ , the twice differentiable real functions  $C^{(2)}(I)$  on  $I$ , etc.). Then  $W$  is a real SUBSPACE of  $V$  if  $W$  is a SUBSET of  $V$  and, for every  $w_1, w_2 \in W$  and  $t \in \mathbb{R}$  (the REALS),  $w_1 + w_2 \in W$  and  $tw_1 \in W$ . Let  $(H)$  be a homogeneous system of linear equations in  $x_1, \dots, x_n$ . Then the SUBSET  $S$  of  $\mathbb{R}^n$  which consists of all solutions of the system  $(H)$  is a subspace of  $\mathbb{R}^n$ .

More generally, let  $F_q$  be a FIELD with  $q = p^\alpha$ , where  $p$  is PRIME, and let  $F_{q,n}$  denote the  $n$ -D VECTOR SPACE over  $F_q$ . The number of  $k$ -D linear subspaces of  $F_{q,n}$  is

$$N(F_{q,n}) = \binom{n}{k}_q,$$

where this is the  $q$ -BINOMIAL COEFFICIENT (Aigner 1979, Exton 1983). The asymptotic limit is

$$N(F_{q,n}) = \begin{cases} c_e q^{n^2/4} [1 + o(1)] & \text{for } n \text{ even} \\ c_o q^{n^2/4} [1 + o(1)] & \text{for } n \text{ odd,} \end{cases}$$

where

$$c_e = \frac{\sum_{k=-\infty}^{\infty} q^{-k^2}}{\prod_{j=1}^{\infty} (1 - q^{-j})}$$

$$c_o = \frac{\sum_{k=-\infty}^{\infty} q^{-(k+1/2)^2}}{\prod_{j=1}^{\infty} (1 - q^{-j})}$$

(Finch). The case  $q = 2$  gives the  $q$ -ANALOG of the WALLIS FORMULA.

see also  $q$ -BINOMIAL COEFFICIENT, SUBFIELD, SUBMANIFOLD

**Substitution Group**

see PERMUTATION GROUP

**Substitution Map**

A MAP which uses a set of rules to transform elements of a sequence into a new sequence using a set of rules which "translate" from the original sequence to its transformation. For example, the substitution map  $\{1 \rightarrow 0, 0 \rightarrow 11\}$  would take 10 to 011.

see also GOLDEN RATIO, MORSE-THUE SEQUENCE, STRING REWRITING, THUE CONSTANT

**Subtend**

Given a geometric object  $O$  in the PLANE and a point  $P$ , let  $A$  be the ANGLE from one edge of  $O$  to the other with VERTEX at  $P$ . Then  $O$  is said to subtend an ANGLE  $A$  from  $P$ .

see also ANGLE, VERTEX ANGLE

**Subtraction**

Subtraction is the operation of taking the DIFFERENCE  $x - y$  of two numbers  $x$  and  $y$ . Here, the symbol between the  $x$  and  $y$  is called the MINUS SIGN and  $x - y$  is read " $x$  MINUS  $y$ ."

see also ADDITION, DIVISION, MINUS, MINUS SIGN, MULTIPLICATION

**Succeeds**

The relationship  $x$  succeeds (or FOLLOWS)  $y$  is written  $x \succ y$ . The relation  $x$  succeeds or is equal to  $y$  is written  $x \succeq y$ .

see also PRECEDES

**Successes**

see DIFFERENCE OF SUCCESSSES

**Sufficient**

A **CONDITION** which, if true, guarantees that a result is also true. (However, the result may also be true if the **CONDITION** is not met.) If a **CONDITION** is both **NECESSARY** and **SUFFICIENT**, then the result is said to be true **IFF** ("if and only if") the **CONDITION** holds.

For example, the condition that a decimal number  $n$  end in the **DIGIT** 2 is a sufficient but not **NECESSARY** condition that  $n$  be **EVEN**.

see also **IFF**, **IMPLIES**, **NECESSARY**

**Suitable Number**

see **IDONEAL NUMBER**

**Sum**

A sum is the result of an **ADDITION**. For example, adding 1, 2, 3, and 4 gives the sum 10, written

$$1 + 2 + 3 + 4 = 10. \quad (1)$$

The numbers being summed are called **ADDENDS**, or sometimes **SUMMANDS**. The summation operation can also be indicated using a capital sigma with upper and lower limits written above and below, and the index indicated below. For example, the above sum could be written

$$\sum_{k=1}^4 k = 10. \quad (2)$$

A simple graphical proof of the sum  $\sum_{k=1}^n k = n(n+1)/2$  can also be given. Construct a sequence of stacks of boxes, each 1 unit across and  $k$  units high, where  $k = 1, 2, \dots, n$ . Now add a rotated copy on top, as in the above figure. Note that the resulting figure has **WIDTH**  $n$  and **HEIGHT**  $n+1$ , and so has **AREA**  $n(n+1)$ . The desired sum is half this, so the **AREA** of the boxes in the sum is  $n(n+1)/2$ . Since the boxes are of unit width, this is also the value of the sum.

The sum can also be computed using the first **EULER-MACLAURIN INTEGRATION FORMULA**

$$\sum_{k=1}^n f(k) = \int_1^n f(x) dx + \frac{1}{2}f(1) + \frac{1}{2}f(n) + \frac{1}{24}B_2[f'(n) - f'(1)] + \dots \quad (3)$$

with  $f(k) = k$ . Then

$$\begin{aligned} \sum_{k=1}^n k &= \int_1^n x dx + \frac{1}{2} \cdot 1 + \frac{1}{2} \cdot n + \frac{1}{6}(1-1) + \dots \\ &= \frac{1}{2}(n^2 - 1) - \frac{1}{2} + h + \frac{1}{2}n = \frac{1}{2}n(n+1). \end{aligned} \quad (4)$$

The general finite sum of integral **POWERS** can be given by the expression

$$\sum_{k=1}^n k^p = \frac{(B+n+1)^{[p+1]} - B^{[p+1]}}{p+1}, \quad (5)$$

where the **NOTATION**  $B^{[k]}$  means the quantity in question is raised to the appropriate **POWER**  $k$  and all terms of the form  $B^m$  are replaced with the corresponding **BERNOULLI NUMBERS**  $B_m$ . It is also true that the **COEFFICIENTS** of the terms in such an expansion sum to 1, as stated by Bernoulli without proof (Boyer 1943).

An analytic solution for a sum of **POWERS** of integers is

$$\sum_{k=1}^n k^p = \zeta(-p) - \zeta(-p, 1+n), \quad (6)$$

where  $\zeta(z)$  is the **RIEMANN ZETA FUNCTION** and  $\zeta(z; a)$  is the **HURWITZ ZETA FUNCTION**. For the special case of  $p$  a **POSITIVE** integer, **FAULHABER'S FORMULA** gives the **SUM** explicitly as

$$\sum_{k=1}^n k^p = \frac{1}{p+1} \sum_{k=1}^{p+1} (-1)^{\delta_{kp}} \binom{p+1}{k} B_{p+1-k} n^k, \quad (7)$$

where  $\delta_{kp}$  is the **KRONECKER DELTA**,  $\binom{n}{k}$  is a **BINOMIAL COEFFICIENT**, and  $B_k$  is a **BERNOULLI NUMBER**. Written explicitly in terms of a sum of **POWERS**,

$$\sum_{k=1}^n k^p = \frac{B_k p!}{k!(p-k+1)!} n^{p-k+1}. \quad (8)$$

Computing the sums for  $p = 1, \dots, 10$  gives

$$\sum_{k=1}^n k = \frac{1}{2}(n^2 + n) \quad (9)$$

$$\sum_{k=1}^n k^2 = \frac{1}{6}(2n^3 + 3n^2 + n) \quad (10)$$

$$\sum_{k=1}^n k^3 = \frac{1}{4}(n^4 + 2n^3 + n^2) \quad (11)$$

$$\sum_{k=1}^n k^4 = \frac{1}{30}(6n^5 + 15n^4 + 10n^3 - n) \quad (12)$$

$$\sum_{k=1}^n k^5 = \frac{1}{12}(2n^6 + 6n^5 + 5n^4 - n^2) \quad (13)$$

$$\sum_{k=1}^n k^6 = \frac{1}{42}(6n^7 + 21n^6 + 21n^5 - 7n^3 + n) \quad (14)$$

$$\sum_{k=1}^n k^7 = \frac{1}{24}(3n^8 + 12n^7 + 14n^6 - 7n^4 + 2n^2) \quad (15)$$

$$\sum_{k=1}^n k^8 = \frac{1}{90}(10n^9 + 45n^8 + 60n^7 - 42n^5 + 20n^3 - 3n) \quad (16)$$

$$\sum_{k=1}^n k^9 = \frac{1}{20}(2n^{10} + 10n^9 + 15n^8 - 14n^6 + 10n^4 - 3n^2) \quad (17)$$

$$\sum_{k=1}^n k^{10} = \frac{1}{66}(6n^{11} + 33n^{10} + 55n^9 - 66n^7 + 66n^5 - 33n^3 + 5n). \quad (18)$$

Factoring the above equations results in

$$\sum_{k=1}^n k = \frac{1}{2}n(n+1) \quad (19)$$

$$\sum_{k=1}^n k^2 = \frac{1}{6}n(n+1)(2n+1) \quad (20)$$

$$\sum_{k=1}^n k^3 = \frac{1}{4}n^2(n+1)^2 \quad (21)$$

$$\sum_{k=1}^n k^4 = \frac{1}{30}n(n+1)(2n+1)(3n^2+3n-1) \quad (22)$$

$$\sum_{k=1}^n k^5 = \frac{1}{12}n^2(n+1)^2(2n^2+2n-1) \quad (23)$$

$$\sum_{k=1}^n k^6 = \frac{1}{42}n(n+1)(2n+1)(3n^4+6n^3-3n+1) \quad (24)$$

$$\sum_{k=1}^n k^7 = \frac{1}{24}n^2(n+1)^2(3n^4+6n^3-n^2-4n+2) \quad (25)$$

$$\sum_{k=1}^n k^8 = \frac{1}{90}n(n+1)(2n+1)(5n^6+15n^5+5n^4-15n^3-n^2+9n-3) \quad (26)$$

$$\sum_{k=1}^n k^9 = \frac{1}{20}n^2(n+1)^2(n^2+n-1) \times (2n^4+4n^3-n^2-3n+3) \quad (27)$$

$$\sum_{k=1}^n k^{10} = \frac{1}{66}n(n+1)(2n+1)(n^2+n-1) \times (3n^6+9n^5+2n^4-11n^3+3n^2+10n-5). \quad (28)$$

From the above, note the interesting identity

$$\sum_{k=1}^n k^3 = \left( \sum_{k=1}^n k \right)^2. \quad (29)$$

Sums of the following type can also be done analytically.

$$\left( \sum_{k=0}^{\infty} x^k \right)^2 = \sum_{n=0}^{\infty} \left( \sum_{k=0}^n 1 \right) x^n = \sum_{n=0}^{\infty} (n+1)x^n \quad (30)$$

$$\begin{aligned} \left( \sum_{k=0}^{\infty} x^k \right)^3 &= \sum_{n=0}^{\infty} \left( \sum_{k=0}^n k \right) x^n \\ &= \frac{1}{2} \sum_{n=0}^{\infty} (n+1)(n+2)x^n \end{aligned} \quad (31)$$

$$\begin{aligned} \left( \sum_{k=0}^{\infty} x^k \right)^4 &= \sum_{n=0}^{\infty} \left[ \sum_{k=0}^n \frac{1}{2}(k+1)(k+2) \right] x^n \\ &= \frac{1}{2} \sum_{n=0}^{\infty} \left( \sum_{k=0}^n k^2 + 3k + 2 \right) x^n \\ &= \frac{1}{2} \sum_{n=0}^{\infty} \left[ \frac{1}{6}n(n+1)(2n+1) + 3\frac{1}{2}n(n+1) + 2(n+1) \right] x^n \\ &= \frac{1}{12} \sum_{n=0}^{\infty} (n+1)[n(2n+1) + 9n + 12] x^n \\ &= \frac{1}{12} \sum_{n=0}^{\infty} (n+1)(2n^2 + 10n + 12) x^n \\ &= \frac{1}{6} \sum_{n=0}^{\infty} (n+1)(n+2)(n+3) x^n. \end{aligned} \quad (32)$$

By INDUCTION, the sum for an arbitrary POWER  $p$  is

$$\left( \sum_{k=0}^{\infty} x^k \right)^p = \frac{1}{(p-1)!} \sum_{n=0}^{\infty} \frac{(n+p-1)!}{n!} x^n. \quad (33)$$

Other analytic sums include

$$\left( \sum_{k=0}^n x^k \right)^2 = \frac{1}{(p-1)!} \sum_{k=0}^{2n} \frac{(n-|n-k|+p-1)!}{(n-|n-k|)!} x^k \quad (34)$$

$$\left( \sum_{n=0}^{\infty} a_n x^n \right)^2 = \sum_{n=0}^{\infty} a_n^2 x^{2n} + 2 \sum_{\substack{n=1 \\ i+j=n \\ i < j}}^{\infty} a_i a_j x^n. \quad (35)$$

$$\begin{aligned} \sum xy &= x_1 y_1 + x_1 y_2 + \dots + x_2 y_1 + x_2 y_2 + \dots \\ &= (x_1 + x_2 + \dots) y_1 + (x_1 + x_2 + \dots) y_2 \\ &= \left( \sum x \right) (y_1 + y_2 + \dots) = \sum x \sum y, \end{aligned} \quad (36)$$

so

$$\sum_{i=1}^m \sum_{j=1}^n x_i y_j = \left( \sum_{i=1}^m x_i \right) \left( \sum_{j=1}^n y_j \right). \quad (37)$$

$$\sum_{j=0}^n j x^j = \frac{n x^{n+2} - (n+1) x^{n+1} + x}{(x-1)^2} \quad (38)$$

$$\sum_{j=1}^n \frac{x_j^r}{\prod_{\substack{k=1 \\ k \neq j}}^n (x_j - x_k)} = \begin{cases} 0 & \text{for } 0 \leq r < n-1 \\ 1 & \text{for } r = n-1 \\ \sum_{j=1}^n x_j & \text{for } r = n \end{cases} \quad (39)$$

$$\sum_{k=1}^n \frac{\prod_{\substack{r=1 \\ r \neq k}}^n (x + k - r)}{\prod_{\substack{r=1 \\ r \neq k}}^n (k - r)} = 1 \quad (40)$$

$$(n+1) \sum_{m=1}^n m^k = \sum_{m=1}^n \left[ m^{k+1} + \sum_{p=1}^n \left( \sum_{m=1}^p m^k \right) \right]. \quad (41)$$

To minimize the sum of a set of squares of numbers  $\{x_i\}$  about a given number  $x_0$

$$S \equiv \sum_i (x_i - x_0)^2 = \sum_i x_i^2 - 2x_0 \sum_i x_i + Nx_0^2, \quad (42)$$

take the DERIVATIVE.

$$\frac{d}{dx_0} S = -2 \sum_i x_i + 2Nx_0 = 0. \quad (43)$$

Solving for  $x_0$  gives

$$x_0 \equiv x = \frac{1}{N} \sum_i x_i, \quad (44)$$

so  $S$  is maximized when  $x_0$  is set to the MEAN.

## Sum-Product Number

A sum-product number is a number  $n$  such that the sum of  $n$ 's digits times the product of  $n$ 's digit is  $n$  itself, for example

$$135 = (1 + 3 + 5)(1 \cdot 3 \cdot 5).$$

The only sum-product numbers less than  $10^7$  are 1, 135, and 144.

see also AMENABLE NUMBER

## Sum Rule

$$\frac{d}{dx} [f(x) + g(x)] = f'(x) + g'(x),$$

where  $d/dx$  denotes a derivative and  $f'(x)$  and  $g'(x)$  are the derivatives of  $f$  and  $g$ , respectively.

see also DERIVATIVE

## Summand

see ADDEND

## Summatory Function

For an discrete function  $f(n)$ , the summatory function is defined by

$$F(n) \equiv \sum_{k \in D}^n f(k),$$

where  $D$  is the DOMAIN of the function.

see also DIVISOR FUNCTION, MANGOLDT FUNCTION, MERTENS FUNCTION, RUDIN-SHAPIRO SEQUENCE, TAU FUNCTION, TOTIENT FUNCTION

## Sup

see SUPREMUM, SUPREMUM LIMIT

## Super-3 Number

An INTEGER  $n$  such that  $3n^3$  contains three consecutive 3s in its DECIMAL representation. The first few super-3 numbers are 261, 462, 471, 481, 558, 753, 1036, ... (Sloane's A014569). A. Anderson has conjectured that all numbers ending in 471, 4710, or 47100 are super-3 (Pickover 1995).

For a digit  $d$ , super-3 numbers can be generalized to super- $d$  numbers  $n$  such that  $dn^d$  contains  $d$   $d$ s in its DECIMAL representation. The following table gives the first few super- $d$  numbers for small  $d$ .

$d$	Sloane	Super- $d$ numbers
2	032743	19, 31, 69, 81, 105, 106, 107, 119, ...
3	014569	261, 462, 471, 481, 558, 753, 1036, ...
4	032744	1168, 4972, 7423, 7752, 8431, 10267, ...
5	032745	4602, 5517, 7539, 12955, 14555, 20137, ...
6	032746	27257, 272570, 302693, 323576, ...
7	032747	140997, 490996, 1184321, 1259609, ...
8	032748	185423, 641519, 1551728, 1854230, ...
9	032749	17546133, 32613656, 93568867, ...

**Super Catalan Number**

While the CATALAN NUMBERS are the number of  $p$ -GOOD PATHS from  $(n, n)$  to  $(0, 0)$  which do not cross the diagonal line, the super Catalan numbers count the number of LATTICE PATHS with diagonal steps from  $(n, n)$  to  $(0, 0)$  which do not touch the diagonal line  $x = y$ .

The super Catalan numbers are given by the RECURRENCE RELATION

$$S(n) = \frac{3(2n-3)S(n-1) - (n-3)S(n-2)}{n}$$

(Comtet 1974), with  $S(1) = S(2) = 1$ . (Note that the expression in Vardi (1991, p. 198) contains *two* errors.) A closed form expression in terms of LEGENDRE POLYNOMIALS  $P_n(x)$  is

$$S(n) = \frac{3P_{n-1}(3) - P_{n-2}(3)}{4n}$$

(Vardi 1991, p. 199). The first few super Catalan numbers are 1, 1, 3, 11, 45, 197, ... (Sloane's A001003).

**Superellipse**

A curve of the form

$$\left| \frac{x}{a} \right|^r + \left| \frac{y}{b} \right|^r = 1.$$

where  $r > 2$ . "The" superellipse is sometimes taken as the curve of the above form with  $r = 5/2$ . Superellipses with  $a = b$  are also known as LAMÉ CURVES. The above curves are for  $a = 1$ ,  $b = 2$ , and  $r = 2.5, 3.0$ , and  $3.5$ .

A degenerate superellipse is a superellipse with  $r \leq 2$ . The above curves are for  $a = 1$ ,  $b = 2$ , and  $r = 0.5, 1.0, 1.5$ , and  $2.0$ .

## Superfactorial

The superfactorial of  $n$  is defined by Pickover (1995) as

$$n\mathfrak{S} \equiv \underbrace{n!^{n!^{\cdots n!}}}_{n!}.$$

The first two values are 1 and 4, but subsequently grow so rapidly that 3 $\mathfrak{S}$  already has a huge number of digits.

Sloane and Plouffe (1995) define the superfactorial by

$$n\mathfrak{S} \equiv \prod_{i=1}^n i!,$$

which is equivalent to the integral values of the  $G$ -FUNCTION. The first few values are 1, 1, 2, 12, 288, 34560, ... (Sloane's A000178).

see also FACTORIAL,  $G$ -FUNCTION, LARGE NUMBER, SUBFACTORIAL

## Supernormal

Trials for which the LEXIS RATIO

$$L \equiv \frac{\sigma}{\sigma_B},$$

satisfies  $L > 1$ , where  $\sigma$  is the VARIANCE in a set of  $s$  LEXIS TRIALS and  $\sigma_B$  is the VARIANCE assuming BERNOULLI TRIALS.

see also BERNOULLI TRIAL, LEXIS TRIALS, SUBNORMAL

## Superperfect Number

A number  $n$  such that

$$\sigma^2(n) = \sigma(\sigma(n)) = 2n,$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. EVEN superperfect numbers are just  $2^{p-1}$ , where  $M_p = 2^p - 1$  is a MERSENNE PRIME. If any ODD superperfect numbers exist, they are SQUARE NUMBERS and either  $n$  or  $\sigma(n)$  is DIVISIBLE by at least three distinct PRIMES.

More generally, an  $m$ -superperfect number is a number for which  $\sigma^m(n) = 2n$ . For  $m \geq 3$ , there are no EVEN  $m$ -superperfect numbers.

see also MERSENNE NUMBER

## Superposition Principle

For a linear homogeneous ORDINARY DIFFERENTIAL EQUATION, if  $y_1(x)$  and  $y_2(x)$  are solutions, then so is  $y_1(x) + y_2(x)$ .

## Superregular Graph

For a VERTEX  $x$  of a GRAPH, let  $\Gamma_x$  and  $\Delta_x$  denote the SUBGRAPHS of  $\Gamma - x$  induced by the VERTICES adjacent to and nonadjacent to  $x$ , respectively. The empty graph is defined to be superregular, and  $\Gamma$  is said to be superregular if  $\Gamma$  is a REGULAR GRAPH and both  $\Gamma_x$  and  $\Delta_x$  are superregular for all  $x$ .

The superregular graphs are precisely  $C_5$ ,  $mK_n$  ( $m, n \geq 1$ ),  $G_n$  ( $n \geq 1$ ), and the complements of these graphs, where  $C_n$  is a CYCLIC GRAPH,  $K_n$  is a COMPLETE GRAPH and  $mK_n$  is  $m$  disjoint copies of  $K_n$ , and  $G_n$  is the Cartesian product of  $K_n$  with itself (the graph whose VERTEX set consists of  $n^2$  VERTICES arranged in an  $n \times n$  square with two VERTICES adjacent IFF they are in the same row or column).

## Superscript

A quantity displayed above the normal line of text (and generally in a smaller point size), as the "i" in  $x^i$ , is called a superscript. Superscripts are commonly used to indicate raising to a POWER ( $x^3$  means  $x \cdot x \cdot x$  or  $x$  CUBED), multiple differentiation ( $f^{(3)}(x)$  is an abbreviation for  $f'''(x) = d^3f/dx^3$ ), and a host of other operations and notations in mathematics.

see also SUBSCRIPT

## Superset

A SET containing all elements of a smaller SET. If  $B$  is a SUBSET of  $A$ , then  $A$  is a superset of  $B$ , written  $A \supseteq B$ . If  $A$  is a PROPER SUPerset of  $B$ , this is written  $A \supset B$ .

**Supremum**

The supremum of a set is the least upper bound of the set. It is denoted

$$\sup S.$$

On the REAL LINE, the supremum of a set is the same as the supremum of its CLOSURE.

*see also* INFIMUM, SUPREMUM LIMIT

**Supremum Limit**

The limit supremum is used for sequences and nets (as opposed to sets) and is denoted

$$\limsup S.$$

*see also* SUPREMUM

**Surd**

An archaic term for a SQUARE ROOT.

*see also* QUADRATIC SURD, SQUARE ROOT

**Surface**

The word "surface" is an important term in mathematics and is used in many ways. The most common and straightforward use of the word is to denote a 2-D SUBMANIFOLD of 3-D EUCLIDEAN SPACE. Surfaces can range from the very complicated (e.g., FRACTALS such as the MANDELBROT SET) to the very simple (such as the PLANE). More generally, the word "surface" can be used to denote an  $(n - 1)$ -D SUBMANIFOLD of an  $n$ -D MANIFOLD, or in general, any co-dimension 1 subobject in an object (like a BANACH SPACE or an infinite-dimensional MANIFOLD).

Even simple surfaces can display surprisingly counterintuitive properties. For example, the SURFACE OF REVOLUTION of  $y = 1/x$  around the  $x$ -AXIS for  $x \geq 1$  (called GABRIEL'S HORN) has FINITE VOLUME but INFINITE SURFACE AREA.

## Surface Area

Surface area is the AREA of a given surface. Roughly speaking, it is the "amount" of a surface, and has units of distance squares. It is commonly denoted  $S$  for a surface in 3-D, or  $A$  for a region of the plane (in which case it is simply called "the" AREA).

If the surface is PARAMETERIZED using  $u$  and  $v$ , then

$$S = \int_S |\mathbf{T}_u \times \mathbf{T}_v| du dv, \quad (1)$$

where  $\mathbf{T}_u$  and  $\hat{\mathbf{T}}_v$  are tangent vectors and  $\mathbf{a} \times \mathbf{b}$  is the CROSS PRODUCT.

The surface area given by rotating the curve  $y = f(x)$  from  $x = a$  to  $x = b$  about the  $x$ -axis is

$$S = \int_a^b 2\pi f(x) \sqrt{1 + [f'(x)]^2} dx. \quad (2)$$

If  $z = f(x, y)$  is defined over a region  $R$ , then

$$S = \iint_R \sqrt{\left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2 + 1} dA, \quad (3)$$

where the integral is taken over the entire surface.

The following tables gives surface areas for some common SURFACES. In the first table,  $S$  denotes the lateral surface, and in the second,  $T$  denotes the total surface. In both tables,  $r$  denotes the RADIUS,  $h$  the height,  $p$  the base PERIMETER, and  $s$  the SLANT HEIGHT (Beyer 1987).

Surface	$S$
cone	$\pi r \sqrt{r^2 + h^2}$
conical frustum	$\pi(R_1 + R_2) \sqrt{(R_1 - R_2)^2 + h^2}$
cube	$6a^2$
cylinder	$2\pi rh$
lune	$2r^2\theta$
oblate spheroid	$2\pi a^2 + \frac{\pi b^2}{e} \ln\left(\frac{1+e}{1-e}\right)$
prolate spheroid	$2\pi b^2 + \frac{2\pi ab}{e} \sin^{-1} e$
pyramid	$\frac{1}{2}ps$
pyramidal frustum	$\frac{1}{2}ps$
sphere	$4\pi r^2$
torus	$4\pi^2 Rr$
zone	$2\pi rh$

Surface	$T$
cone	$\pi r(r + \sqrt{r^2 + h^2})$
conical frustum	$\pi[R_1^2 + R_2^2 + (R_1 + R_2)\sqrt{(R_1 - R_2)^2 + h^2}]$
cylinder	$2\pi r(r + h)$

Even simple surfaces can display surprisingly counterintuitive properties. For instance, the surface of revolution of  $y = 1/x$  around the  $x$ -AXIS for  $x \geq 1$  is called GABRIEL'S HORN, and has FINITE VOLUME but INFINITE surface AREA.

see also AREA, SURFACE INTEGRAL, SURFACE OF REVOLUTION, VOLUME

## Surface Integral

For a SCALAR FUNCTION  $f$  over a surface parameterized by  $u$  and  $v$ , the surface integral is given by

$$\Phi = \int_S f da = \int_S f(u, v) |\mathbf{T}_u \times \mathbf{T}_v| du dv, \quad (1)$$

where  $\mathbf{T}_u$  and  $\hat{\mathbf{T}}_v$  are tangent vectors and  $\mathbf{a} \times \mathbf{b}$  is the CROSS PRODUCT.

For a VECTOR FUNCTION over a surface, the surface integral is given by

$$\Phi = \int_S \mathbf{F} \cdot d\mathbf{a} = \int_S (\mathbf{F} \cdot \hat{\mathbf{n}}) da \quad (2)$$

$$= \int_S f_x dy dz + f_y dz dx + f_z dx dy, \quad (3)$$

where  $\mathbf{a} \cdot \mathbf{b}$  is a DOT PRODUCT and  $\hat{\mathbf{n}}$  is a unit NORMAL VECTOR. If  $z = f(x, y)$ , then  $d\mathbf{a}$  is given explicitly by

$$d\mathbf{a} = \pm \left( -\frac{\partial z}{\partial x} \hat{\mathbf{x}} - \frac{\partial z}{\partial y} \hat{\mathbf{y}} + \hat{\mathbf{z}} \right) dx dy. \quad (4)$$

If the surface is SURFACE PARAMETERIZED using  $u$  and  $v$ , then

$$\Phi = \int_S \mathbf{F} \cdot (\mathbf{T}_u \times \mathbf{T}_v) du dv. \quad (5)$$

see also SURFACE PARAMETERIZATION

**Surface Parameterization**

A surface in 3-SPACE can be parameterized by two variables (or coordinates)  $u$  and  $v$  such that

$$x = x(u, v) \quad (1)$$

$$y = y(u, v) \quad (2)$$

$$z = z(u, v). \quad (3)$$

If a surface is parameterized as above, then the tangent VECTORS

$$\mathbf{T}_u = \frac{\partial x}{\partial u} \hat{\mathbf{x}} + \frac{\partial y}{\partial u} \hat{\mathbf{y}} + \frac{\partial z}{\partial u} \hat{\mathbf{z}} \quad (4)$$

$$\mathbf{T}_v = \frac{\partial x}{\partial v} \hat{\mathbf{x}} + \frac{\partial y}{\partial v} \hat{\mathbf{y}} + \frac{\partial z}{\partial v} \hat{\mathbf{z}} \quad (5)$$

are useful in computing the SURFACE AREA and SURFACE INTEGRAL.

see also SMOOTH SURFACE, SURFACE AREA, SURFACE INTEGRAL

**Surface of Revolution**

A surface of revolution is a SURFACE generated by rotating a 2-D CURVE about an axis. The resulting surface therefore always has azimuthal symmetry. Examples of surfaces of revolution include the APPLE, CONE (excluding the base), CONICAL FRUSTUM (excluding the ends), CYLINDER (excluding the ends), DARWIN-DE SITTER SPHEROID, GABRIEL'S HORN, HYPERBOLOID, LEMON, OBLATE SPHEROID, PARABOLOID, PROLATE SPHEROID, PSEUDOSPHERE, SPHERE, SPHEROID, and TORUS (and its generalization, the TOROID).

The standard parameterization of a surface of revolution is given by

$$x(u, v) = \phi(v) \cos u \quad (1)$$

$$y(u, v) = \phi(v) \sin u \quad (2)$$

$$z(u, v) = \psi(v). \quad (3)$$

For a curve so parameterized, the first FUNDAMENTAL FORM has

$$E = \psi^2 \quad (4)$$

$$F = 0 \quad (5)$$

$$G = \phi'^2 + \psi'^2. \quad (6)$$

Wherever  $\phi$  and  $\phi'^2 + \psi'^2$  are nonzero, then the surface is regular and the second FUNDAMENTAL FORM has

$$e = -\frac{|\phi|\psi'}{\sqrt{\phi'^2 + \psi'^2}} \quad (7)$$

$$f = 0 \quad (8)$$

$$g = \frac{\text{sgn}(\phi)(\phi''\psi' - \phi'\psi'')}{\sqrt{\phi'^2 + \psi'^2}}. \quad (9)$$

Furthermore, the unit NORMAL VECTOR is

$$\hat{\mathbf{N}}(u, v) = \frac{\text{sgn}(\phi)}{\sqrt{\phi'^2 + \psi'^2}} \begin{bmatrix} \phi' \cos u \\ \phi' \sin u \\ \phi' \end{bmatrix}, \quad (10)$$

and the PRINCIPAL CURVATURES are

$$\kappa_1 = \frac{g}{G} = \frac{\text{sgn}(\phi)(\phi''\psi' - \phi'\psi'')}{(\phi'^2 + \psi'^2)^{3/2}} \quad (11)$$

$$\kappa_2 = \frac{e}{E} = -\frac{\psi'}{|\phi|\sqrt{\phi'^2 + \psi'^2}}. \quad (12)$$

The GAUSSIAN and MEAN CURVATURES are

$$K = \frac{-\psi'^2\phi'' + \phi'\psi'\psi''}{\phi(\phi'^2 + \psi'^2)^2} \quad (13)$$

$$H = \frac{\phi(\phi''\psi' - \phi'\psi'') - \psi'(\phi'^2 + \psi'^2)}{2|\phi|(\phi'^2 + \psi'^2)^{3/2}} \quad (14)$$

(Gray 1993).

PAPPUS'S CENTROID THEOREM gives the VOLUME of a solid of rotation as the cross-sectional AREA times the distance traveled by the centroid as it is rotated.

CALCULUS OF VARIATIONS can be used to find the curve from a point  $(x_1, y_1)$  to a point  $(x_2, y_2)$  which, when revolved around the  $x$ -AXIS, yields a surface of smallest SURFACE AREA  $A$  (i.e., the MINIMAL SURFACE). This is equivalent to finding the MINIMAL SURFACE passing through two circular wire frames. The AREA element is

$$dA = 2\pi y ds = 2\pi y \sqrt{1 + y'^2} dx, \quad (15)$$

so the SURFACE AREA is

$$A = 2\pi \int y \sqrt{1 + y'^2} dx, \quad (16)$$

and the quantity we are minimizing is

$$f = y \sqrt{1 + y'^2}. \quad (17)$$

This equation has  $f_x = 0$ , so we can use the BELTRAMI IDENTITY

$$f - y_x \frac{\partial f}{\partial y_x} = a \quad (18)$$

to obtain

$$y \sqrt{1 + y'^2} - y' \frac{yy'}{\sqrt{1 + y'^2}} = a \quad (19)$$

$$y(1 + y'^2) - yy'^2 = a \sqrt{1 + y'^2} \quad (20)$$

$$y = a \sqrt{1 + y'^2} \quad (21)$$

$$\frac{y}{\sqrt{1 + y'^2}} = a \quad (22)$$

$$\frac{y^2}{a} - 1 = y'^2 \quad (23)$$

$$\frac{dx}{dy} = \frac{1}{y'} = \frac{a}{\sqrt{y^2 - a^2}} \quad (24)$$

$$x = a \int \frac{dy}{\sqrt{y^2 - a^2}} = a \cosh^{-1} \left( \frac{y}{a} \right) + b \quad (25)$$

$$y = a \cosh \left( \frac{x - b}{a} \right), \quad (26)$$

which is called a CATENARY, and the surface generated by rotating it is called a CATENOID. The two constants  $a$  and  $b$  are determined from the two implicit equations

$$y_1 = a \cosh \left( \frac{x_1 - b}{a} \right) \quad (27)$$

$$y_2 = a \cosh \left( \frac{x_2 - b}{a} \right), \quad (28)$$

which cannot be solved analytically.

The general case is somewhat more complicated than this solution suggests. To see this, consider the MINIMAL SURFACE between two rings of equal RADIUS  $y_0$ . Without loss of generality, take the origin at the midpoint of the two rings. Then the two endpoints are located at  $(-x_0, y_0)$  and  $(x_0, y_0)$ , and

$$y_0 = a \cosh \left( \frac{-x_0 - b}{a} \right) = a \cosh \left( \frac{x_0 - b}{a} \right). \quad (29)$$

But  $\cosh(-x) = \cosh(x)$ , so

$$\cosh \left( \frac{-x_0 - b}{a} \right) = \cosh \left( \frac{-x_0 + b}{a} \right). \quad (30)$$

Inverting each side

$$-x_0 - b = -x_0 + b, \quad (31)$$

so  $b = 0$  (as it must by symmetry, since we have chosen the origin between the two rings), and the equation of the MINIMAL SURFACE reduces to

$$y = a \cosh \left( \frac{x}{a} \right). \quad (32)$$

At the endpoints

$$y_0 = a \cosh \left( \frac{x_0}{a} \right), \quad (33)$$

but for certain values of  $x_0$  and  $y_0$ , this equation has no solutions. The physical interpretation of this fact is that the surface breaks and forms circular disks in each ring to minimize AREA. CALCULUS OF VARIATIONS cannot be used to find such discontinuous solutions (known in this case as GOLDSCHMIDT SOLUTIONS). The minimal surfaces for several choices of endpoints are shown above. The first two cases are CATENOIDS, while the third case is a GOLDSCHMIDT SOLUTION.

To find the maximum value of  $x_0/y_0$  at which CATENARY solutions can be obtained, let  $p \equiv 1/a$ . Then (31) gives

$$y_0 p = \cosh(p x_0). \quad (34)$$

Now, denote the maximum value of  $x_0$  as  $x_0^*$ . Then it will be true that  $dx_0/dp = 0$ . Take  $d/dp$  of (34),

$$y_0 = \sinh(p x_0) \left( x_0 + p \frac{dx_0}{dp} \right). \quad (35)$$

Now set  $dx_0/dp = 0$

$$y_0 = x_0 \sinh(p x_0^*). \quad (36)$$

From (34),

$$p y_0^* = \cosh(p x_0^*). \quad (37)$$

Take (37)  $\div$  (36),

$$p x_0^* = \coth(p x_0^*). \quad (38)$$

Defining  $u \equiv p x_0^*$ ,

$$u = \coth u. \quad (39)$$

This has solution  $u = 1.1996789403 \dots$ . From (36),  $y_0 p = \cosh u$ . Divide this by (39) to obtain  $y_0/x_0 = \sinh u$ , so the maximum possible value of  $x_0/y_0$  is

$$\frac{x_0}{y_0} = \operatorname{csch} u = 0.6627434193 \dots \quad (40)$$

Therefore, only Goldschmidt ring solutions exist for  $x_0/y_0 > 0.6627 \dots$

The SURFACE AREA of the minimal CATENOID surface is given by

$$A = 2(2\pi) \int_0^{x_0} y \sqrt{1 + y'^2} dx, \quad (41)$$

but since

$$y = \sqrt{1 + y'^2} a \quad (42)$$

$$y = a \cosh \left( \frac{x}{a} \right), \quad (43)$$

$$\begin{aligned}
A &= \frac{4\pi}{a} \int_0^{x_0} y^2 dx = 4\pi a \int_0^{x_0} \cosh^2\left(\frac{x}{a}\right) dx \\
&= 4\pi a \int_0^{x_0} \frac{1}{2} \left[ \cosh\left(\frac{2x}{a}\right) + 1 \right] dx \\
&= 2\pi a \left[ \int_0^{x_0} \cosh\left(\frac{2x}{a}\right) dx + \int_0^{x_0} dx \right] \\
&= 2\pi a \left[ \frac{a}{2} \sinh\left(\frac{2x}{a}\right) + x \right]_0^{x_0} \\
&= \pi a^2 \left[ \sinh\left(\frac{2x}{a}\right) + \frac{2x}{a} \right]_0^{x_0} \\
&= \pi a^2 \left[ \sinh\left(\frac{2x_0}{a}\right) + \frac{2x_0}{a} \right]. \quad (44)
\end{aligned}$$

Some caution is needed in solving (33) for  $a$ . If we take  $x_0 = 1/2$  and  $y_0 = 1$  then (33) becomes

$$1 = a \cosh\left(\frac{1}{2a}\right), \quad (45)$$

which has *two* solutions:  $a_1 = 0.2350\dots$  ("deep"), and  $a_2 = 0.8483\dots$  ("flat"). However, upon plugging these into (44) with  $x_0 = 1/2$ , we find  $A_1 = 6.8456\dots$  and  $A_2 = 5.9917\dots$ . So  $A_1$  is *not*, in fact, a local minimum, and  $A_2$  is the only *true* minimal solution.

The SURFACE AREA of the CATENOID solution equals that of the GOLDSCHMIDT SOLUTION when (44) equals the AREA of two disks,

$$\pi a^2 \left[ \sinh\left(\frac{2x_0}{a}\right) + \frac{2x_0}{a} \right] = 2\pi y_0^2 \quad (46)$$

$$a^2 \left[ 2 \sinh\left(\frac{x_0}{a}\right) \cosh\left(\frac{x_0}{a}\right) + \frac{2x_0}{a} \right] - 2y_0^2 = 0 \quad (47)$$

$$a^2 \left[ \cosh\left(\frac{x_0}{a}\right) \sqrt{\cosh^2\left(\frac{x_0}{a}\right) - 1} + \frac{x_0}{a} \right] - y_0^2 = 0. \quad (48)$$

Plugging in

$$\frac{y_0}{a} = \cosh\left(\frac{x_0}{a}\right), \quad (49)$$

$$\frac{y_0}{a} \sqrt{\left(\frac{y_0}{a}\right)^2 - 1} + \cosh^{-1}\left(\frac{y_0}{a}\right) - \left(\frac{y_0}{a}\right)^2 = 0. \quad (50)$$

Defining

$$u \equiv \frac{y_0}{a} \quad (51)$$

gives

$$u \sqrt{u^2 - 1} + \cosh^{-1} u - u^2 = 0. \quad (52)$$

This has a solution  $u = 1.2113614259$ . The value of  $x_0/y_0$  for which

$$A_{\text{catenary}} = A_{\text{2 disks}} \quad (53)$$

is therefore

$$\frac{x_0}{y_0} = \frac{\frac{x_0}{a}}{\frac{y_0}{a}} = \frac{\cosh^{-1}\left(\frac{y_0}{a}\right)}{\frac{y_0}{a}} = \frac{\cosh^{-1} u}{u} = 0.5276973967. \quad (54)$$

For  $x_0/y_0 \in (0.52770, 0.6627)$ , the CATENARY solution has larger AREA than the two disks, so it exists only as a RELATIVE MINIMUM.

There also exist solutions with a disk (of radius  $r$ ) between the rings supported by two CATENOIDS of revolution. The AREA is larger than that for a simple CATENOID, but it is a RELATIVE MINIMUM. The equation of the POSITIVE half of this curve is

$$y = c_1 \cosh\left(\frac{x}{c_1} + c_3\right). \quad (55)$$

At  $(0, r)$ ,

$$r = c_1 \cosh(c_3). \quad (56)$$

At  $(x_0, y_0)$ ,

$$y_0 = c_1 \cosh\left(\frac{x_0}{c_1} + c_3\right). \quad (57)$$

The AREA of the two CATENOIDS is

$$\begin{aligned}
A_{\text{catenoids}} &= 2(2\pi) \int_0^{x_0} y \sqrt{1 + y'^2} dx = \frac{4\pi}{c_1} \int_0^{x_0} y^2 dx \\
&= 4\pi c_1 \int_0^{x_0} \cosh^2\left(\frac{x}{c_1} + c_3\right) dx. \quad (58)
\end{aligned}$$

Now let  $u \equiv x/c_1 + c_3$ , so  $du = dx/c_1$

$$\begin{aligned}
A &= 4\pi c_1^2 \int_{c_3}^{x_0/x_1 + c_3} \cosh^2 u du \\
&= 4\pi c_1^2 \frac{1}{2} \int_{c_3}^{x_0/x_1 + c_3} [\cosh(2u) + 1] du \\
&= 2\pi c_1^2 \left[ \frac{1}{2} \sinh(2u) + u \right]_{c_3}^{x_0/x_1 + c_3} \\
&= 2\pi c_1^2 \left\{ \frac{1}{2} \sinh \left[ 2 \left( \frac{x_0}{c_1} + c_3 \right) \right] - \frac{1}{2} \sinh(2c_3) + \frac{x_0}{c_1} \right\} \\
&= \pi c_1^2 \left\{ \sinh \left[ 2 \left( \frac{x_0}{c_1} + c_3 \right) \right] - \sinh(2c_3) + \frac{2x_0}{c_1} \right\}. \quad (59)
\end{aligned}$$

The AREA of the central DISK is

$$A_{\text{disk}} = \pi r^2 = \pi c_1^2 \cosh^2 c_3, \quad (60)$$

so the total AREA is

$$A = \pi c_1^2 \left\{ \sinh \left[ 2 \left( \frac{x_0}{c_1} + c_3 \right) \right] + [\cosh^2 c_3 - \sinh(2c_3)] + \frac{2x_0}{c_1} \right\}. \quad (61)$$

By PLATEAU'S LAWS, the CATENOIDs meet at an ANGLE of  $120^\circ$ , so

$$\begin{aligned} \tan 30^\circ &= \left[ \frac{dy}{dx} \right]_{x=0} = \left[ \sinh \left( \frac{x}{c_1} + c_3 \right) \right]_{x=0} \\ &= \sinh c_3 = \frac{1}{\sqrt{3}} \end{aligned} \quad (62)$$

and

$$c_3 = \sinh^{-1} \left( \frac{1}{\sqrt{3}} \right). \quad (63)$$

This means that

$$\begin{aligned} \cosh^2 c_3 - \sinh(2c_3) &= [1 + \sinh^2 c_3] - 2 \sinh c_3 \sqrt{1 + \sinh^2 c_3} \\ &= (1 + \tfrac{1}{3}) - 2 \left( \frac{1}{\sqrt{3}} \right) \sqrt{1 + \tfrac{1}{3}} \\ &= \frac{4}{3} - \frac{2}{\sqrt{3}} \frac{2}{\sqrt{3}} = 0, \end{aligned} \quad (64)$$

so

$$A = \pi c_1^2 \left\{ \sinh \left[ 2 \left( \frac{x_0}{c_1} + c_3 \right) \right] + \frac{2x_0}{c_1} \right\}. \quad (65)$$

Now examine  $x_0/y_0$ ,

$$\frac{x_0}{y_0} = \frac{\frac{x_0}{c_1}}{\frac{y_0}{c_1}} = \frac{\frac{x_0}{c_1}}{\cosh \left( \frac{x_0}{c_1} + c_3 \right)} = u \operatorname{sech}(u + c_3), \quad (66)$$

where  $u \equiv x_0/c_1$ . Finding the maximum ratio of  $x_0/y_0$  gives

$$\frac{d}{du} \left( \frac{x_0}{y_0} \right) = \operatorname{sech}(u + c_3) - u \tanh(u + c_3) \operatorname{sech}(u + c_3) = 0 \quad (67)$$

$$u \tanh(u + c_3) = 1, \quad (68)$$

with  $c_3 = \sinh^{-1}(1/\sqrt{3})$  as given above. The solution is  $u = 1.0799632187$ , so the maximum value of  $x_0/y_0$  for two CATENOIDs with a central disk is  $y_0 = 0.4078241702$ .

If we are interested instead in finding the curve from a point  $(x_1, y_1)$  to a point  $(x_2, y_2)$  which, when revolved around the  $y$ -AXIS (as opposed to the  $x$ -AXIS), yields a surface of smallest SURFACE AREA  $A$ , we proceed as above. Note that the solution is physically equivalent to that for rotation about the  $x$ -AXIS, but takes on a different mathematical form. The AREA element is

$$dA = 2\pi x ds = 2\pi x \sqrt{1 + y'^2} dx \quad (69)$$

$$A = 2\pi \int x \sqrt{1 + y'^2} dx, \quad (70)$$

and the quantity we are minimizing is

$$f = x \sqrt{1 + y'^2}. \quad (71)$$

Taking the derivatives gives

$$\frac{\partial f}{\partial y} = 0 \quad (72)$$

$$\frac{d}{dx} \frac{\partial f}{\partial y'} = \frac{d}{dx} \left( \frac{xy'}{\sqrt{1 + y'^2}} \right), \quad (73)$$

so the EULER-LAGRANGE DIFFERENTIAL EQUATION becomes

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \frac{\partial f}{\partial y'} = \frac{d}{dx} \left( \frac{xy'}{\sqrt{1 + y'^2}} \right) = 0. \quad (74)$$

$$\frac{xy'}{\sqrt{1 + y'^2}} = a \quad (75)$$

$$x^2 y'^2 = a^2 (1 + y'^2) \quad (76)$$

$$y'^2 (x^2 - a^2) = a^2 \quad (77)$$

$$\frac{dy}{dx} = \frac{a}{\sqrt{x^2 - a^2}} \quad (78)$$

$$y = a \int \frac{dx}{\sqrt{x^2 - a^2}} + b = a \cosh^{-1} \left( \frac{x}{a} \right) + b. \quad (79)$$

Solving for  $x$  then gives

$$x = a \cosh \left( \frac{y - b}{a} \right), \quad (80)$$

which is the equation for a CATENARY. The SURFACE AREA of the CATENOID product by rotation is

$$\begin{aligned} A &= 2\pi \int x \sqrt{1 + y'^2} dx = 2\pi \int x \sqrt{1 + \frac{a^2}{x^2 - a^2}} dx \\ &= 2\pi \int \frac{x}{\sqrt{x^2 - a^2}} \sqrt{(x^2 - a^2) + a^2} dx \\ &= 2\pi \int \frac{x^2 dx}{\sqrt{x^2 - a^2}} \\ &= \left[ \frac{x}{2} \sqrt{x^2 - a^2} + \frac{a^2}{2} \ln \left( x + \sqrt{x^2 - a^2} \right) \right]_{x_1}^{x_2} \\ &= \frac{1}{2} \left[ x_2 \sqrt{x_2^2 - a^2} - x_1 \sqrt{x_1^2 - a^2} \right. \\ &\quad \left. + a^2 \ln \left( \frac{x_2 + \sqrt{x_2^2 - a^2}}{x_1 + \sqrt{x_1^2 - a^2}} \right) \right]. \end{aligned} \quad (81)$$

Isenberg (1992, p. 80) discusses finding the MINIMAL SURFACE passing through two rings with axes offset from each other.

### Surface of Section

A surface (or "space") of section is a way of presenting a trajectory in  $n$ -D PHASE SPACE in an  $(n - 1)$ -D SPACE. By picking one phase element constant and plotting the values of the other elements each time the selected element has the desired value, an intersection surface is obtained. If the equations of motion can be formulated as a MAP in which an explicit FORMULA gives the values of the other elements at successive passages through the selected element value, the time required to compute the surface of section is greatly reduced.

see also PHASE SPACE

### Surgery

In the process of attaching a  $k$ -HANDLE to a MANIFOLD  $M$ , the BOUNDARY of  $M$  is modified by a process called  $(k - 1)$ -surgery. Surgery consists of the removal of a TUBULAR NEIGHBORHOOD of a  $(k - 1)$ -SPHERE  $S^{k-1}$  from the BOUNDARIES of  $M$  and the  $\dim(M) - 1$  standard SPHERE, and the gluing together of these two scarred-up objects along their common BOUNDARIES.

### Surreal Number

The most natural collection of numbers which includes both the REAL NUMBERS and the infinite ORDINAL NUMBERS of Georg Cantor. They were invented by John H. Conway in 1969. Every REAL NUMBER is surrounded by surreals, which are closer to it than any REAL NUMBER. Knuth (1974) describes the surreal numbers in a work of fiction.

The surreal numbers are written using the NOTATION  $\{a|b\}$ , where  $\{\} = 0$ ,  $\{0\} = 1$  is the simplest number greater than 0,  $\{1\} = 2$  is the simplest number greater than 1, etc. Similarly,  $\{0\} = -1$  is the simplest number less than 1, etc. However, 2 can also be represented by  $\{1|3\}$ ,  $\{3/2|4\}$ ,  $\{1|\omega\}$ , etc.

see also OMNIFIC INTEGER, ORDINAL NUMBER, REAL NUMBER

### Surrogate

Surrogate data are artificially generated data which mimic statistical properties of real data. Isospectral surrogates have identical POWER SPECTRA as real data but with randomized phases. Scrambled surrogates have the same probability distribution as real data, but with white noise POWER SPECTRA.

see also POWER SPECTRUM

### Surveying Problems

see HANSEN'S PROBLEM, SNELLIUS-POTHENOT PROBLEM

### Survivorship Curve

Plotting  $l_x$  from a LIFE EXPECTANCY table on a logarithmic scale versus  $x$  gives a curve known as a survivorship curve. There are three general classes of survivorship curves, illustrated above.

1. Type I curves are typical of populations in which most mortality occurs among the elderly (e.g., humans in developed countries).
2. Type II curves occur when mortality is not dependent on age (e.g., many species of large birds and fish). For an infinite type II population,  $e_0 = e_1 = \dots$ , but this cannot hold for a finite population.
3. Type III curves occur when juvenile mortality is extremely high (e.g., plant and animal species producing many offspring of which few survive). In type III populations, it is often true that  $e_{i+1} > e_i$  for small  $i$ . In other words, life expectancy increases for individuals who survive their risky juvenile period.

see also LIFE EXPECTANCY

### Suslin's Theorem

A SET in a POLISH SPACE is a BOREL SET IFF it is both ANALYTIC and COANALYTIC. For subsets of  $w$ , a set is  $\delta_1^1$  IFF it is "hyperarithmetical."

see also ANALYTIC SET, BOREL SET, COANALYTIC SET, POLISH SPACE

### Suspended Knot

An ordinary KNOT in 3-D suspended in 4-D to create a knotted 2-sphere. Suspended knots are not smooth at the poles.

see also SPUN KNOT, TWIST-SPUN KNOT

### Suspension

The JOIN of a TOPOLOGICAL SPACE  $X$  and a pair of points  $S^0$ ,  $\Sigma(X) = X * S^0$ .

### Suzanne Set

The  $n$ th Suzanne set  $S_n$  is defined as the set of COMPOSITE NUMBERS  $x$  for which  $n|S(x)$  and  $n|S_p(x)$ , where

$$x = a_0 + a_1(10^1) + \dots + a_d(10^d) = p_1 p_2 \dots p_n,$$

and

$$S(x) = \sum_{j=0}^d a_j$$

$$S_p(x) = \sum_{i=1}^m S(p_i).$$

Every Suzanne set has an infinite number of elements. The Suzanne set  $S_n$  is a superset of the MONICA SET  $M_n$ .

**Swinnerton-Dyer Conjecture**

In the early 1960s, B. Birch and H. P. F. Swinnerton-Dyer conjectured that if a given ELLIPTIC CURVE has an infinite number of solutions, then the associated  $L$ -function has value 0 at a certain fixed point. In 1976, Coates and Wiles showed that elliptic curves with COMPLEX multiplication having an infinite number of solutions have  $L$ -functions which are zero at the relevant fixed point (COATES-WILES THEOREM), but they were unable to prove the converse. V. Kolyvagin extended this result to modular curves.

**Swirl**

A swirl is a generic word to describe a function having arcs which double back swirl around each other. The plots above correspond to the function

$$f(r, \theta) = \sin(6 \cos r - n\theta)$$

for  $n = 0, 1, \dots, 5$ .

see also DAISY, WHIRL

**Sylow  $p$ -Subgroup**

If  $p^k$  is the highest POWER of a PRIME  $p$  dividing the ORDER of a finite GROUP  $G$ , then a SUBGROUP of  $G$  of ORDER  $p^k$  is called a Sylow  $p$ -subgroup of  $G$ .

see also ABHYANKAR'S CONJECTURE, SUBGROUP, SYLOW THEOREMS

**Sylow Theorems**

Let  $p$  be a PRIME NUMBER,  $G$  a GROUP, and  $|G|$  the order of  $G$ .

1. If  $p$  divides  $|G|$ , then  $G$  has a SYLOW  $p$ -SUBGROUP.
2. In a FINITE GROUP, all the SYLOW  $p$ -SUBGROUPS are isomorphic for some fixed  $p$ .
3. The number of SYLOW  $p$ -SUBGROUPS for a fixed  $p$  is CONGRUENT to 1 (mod  $p$ ).

**Sylvester Cyclotomic Number**

Given a LUCAS SEQUENCE with parameters  $P$  and  $Q$ , discriminant  $D \neq 0$ , and roots  $\alpha$  and  $\beta$ , the Sylvester cyclotomic numbers are

$$Q_n = \prod_r (\alpha - \zeta^r \beta),$$

where

$$\zeta \equiv \cos\left(\frac{2\pi}{n}\right) + i \sin\left(\frac{2\pi}{n}\right)$$

is a PRIMITIVE ROOT OF UNITY and the product is over all exponents  $r$  RELATIVELY PRIME to  $n$  such that  $r \in [1, n)$ .

see also LUCAS SEQUENCE

**Sylvester's Inertia Law**

The numbers of EIGENVALUES that are POSITIVE, NEGATIVE, or 0 do not change under a congruence transformation. Gradshteyn and Ryzhik (1979) state it as follows: when a QUADRATIC FORM  $Q$  in  $n$  variables is reduced by a nonsingular linear transformation to the form

$$Q = y_1^2 + y_2^2 + \dots + y_p^2 - y_{p+1}^2 - y_{p+2}^2 - \dots - y_r^2,$$

the number  $p$  of POSITIVE SQUARES appearing in the reduction is an invariant of the QUADRATIC FORM  $Q$  and does not depend on the method of reduction.

see also EIGENVALUE, QUADRATIC FORM

References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products*, 5th ed. San Diego, CA: Academic Press, p. 1105, 1979.

**Sylvester's Line Problem**

It is not possible to arrange a finite number of points so that a LINE through every two of them passes through a third, unless they are all on a single LINE.

see also COLLINEAR, SYLVESTER'S FOUR-POINT PROBLEM

**Sylvester Matrix**

For POLYNOMIALS of degree  $m$  and  $n$ , the Sylvester matrix is an  $(m+n) \times (m+n)$  matrix whose DETERMINANT is the RESULTANT of the two POLYNOMIALS.

see also RESULTANT

**Sylvester's Sequence**

The sequence defined by  $e_0 = 2$  and the RECURRENCE RELATION

$$e_n = 1 + \prod_{i=0}^{n-1} e_i = e_{n-1}^2 - e_{n-1} + 1. \quad (1)$$

This sequence arises in Euclid's proof that there are an INFINITE number of PRIMES. The proof proceeds by constructing a sequence of PRIMES using the RECURRENCE RELATION

$$e_{n+1} = e_0 e_1 \cdots e_n + 1 \quad (2)$$

(Vardi 1991). Amazingly, there is a constant

$$E \approx 1.264084735306 \quad (3)$$

such that

$$e_n = \left\lfloor E^{2^{n+1}} + \frac{1}{2} \right\rfloor \quad (4)$$

(Vardi 1991, Graham *et al.* 1994). The first few numbers in Sylvester's sequence are 2, 3, 7, 43, 1807, 3263443, 10650056950807, ... (Sloane's A000058). The  $e_n$  satisfy

$$\sum_{n=0}^{\infty} \frac{1}{e_n} = 1. \quad (5)$$

In addition, if  $0 < x < 1$  is an IRRATIONAL NUMBER, then the  $n$ th term of an infinite sum of unit fractions used to represent  $x$  as computed using the GREEDY ALGORITHM must be smaller than  $1/e_n$ .

The  $n$  of the first few PRIME  $e_n$  are 0, 1, 2, 3, 5, .... Vardi (1991) gives a lists of factors less than  $5 \times 10^7$  of  $e_n$  for  $n \leq 200$  and shows that  $e_n$  is COMPOSITE for  $6 \leq n \leq 17$ . Furthermore, all numbers less than  $2.5 \times 10^{15}$  in Sylvester's sequence are SQUAREFREE, and no SQUAREFUL numbers in this sequence are known (Vardi 1991).

### Symmedian Point

see LEMOINE POINT

### Symmetric

A quantity which remains unchanged in SIGN when indices are reversed. For example,  $A_{ij} = a_i + a_j$  is symmetric since  $A_{ij} = A_{ji}$ .

see also ANTISYMMETRIC

### Symmetric Block Design

A symmetric design is a BLOCK DESIGN  $(v, k, \lambda, r, b)$  with the same number of blocks as points, so  $b = v$  (or, equivalently,  $r = k$ ). An example of a symmetric block design is a PROJECTIVE PLANE.

see also BLOCK DESIGN, PROJECTIVE PLANE

### Symmetric Design

see SYMMETRIC BLOCK DESIGN

### Symmetric Function

A symmetric function on  $n$  variables  $x_1, \dots, x_n$  is a function that is unchanged by any PERMUTATION of its variables. In most contexts, the term "symmetric function" refers to a polynomial on  $n$  variables with this feature (more properly called a "symmetric polynomial"). Another type of symmetric functions is symmetric rational functions, which are the RATIONAL FUNCTIONS that are unchanged by PERMUTATION of variables.

The symmetric polynomials (respectively, symmetric rational functions) can be expressed as polynomials (respectively, rational functions) in the ELEMENTARY SYMMETRIC FUNCTIONS. This is called the FUNDAMENTAL THEOREM OF SYMMETRIC FUNCTIONS.

A function  $f(x)$  is sometimes said to be symmetric about the  $y$ -AXIS if  $f(-x) = f(x)$ . Examples of such functions include  $|x|$  (the ABSOLUTE VALUE) and  $x^2$  (the PARABOLA).

see also ELEMENTARY SYMMETRIC FUNCTION, FUNDAMENTAL THEOREM OF SYMMETRIC FUNCTIONS, RATIONAL FUNCTION

### Symmetric Group

The symmetric group  $S_n$  of DEGREE  $n$  is the GROUP of all PERMUTATIONS on  $n$  symbols.  $S_n$  is therefore of ORDER  $n!$  and contains as SUBGROUPS every GROUP of ORDER  $n$ . The number of CONJUGACY CLASSES of  $S_n$  is given by the PARTITION FUNCTION  $P$ .

NETTO'S CONJECTURE states that the probability that two elements  $P_1$  and  $P_2$  of a symmetric group generate the entire group tends to  $3/4$  as  $n \rightarrow \infty$ . This was proven by Dixon in 1967.

see also ALTERNATING GROUP, CONJUGACY CLASS, FINITE GROUP, NETTO'S CONJECTURE, PARTITION FUNCTION  $P$ , SIMPLE GROUP

#### References

### Symmetric Matrix

A symmetric matrix is a SQUARE MATRIX which satisfies  $A^T = A$  where  $A^T$  denotes the TRANSPOSE, so  $a_{ij} = a_{ji}$ . This also implies

$$A^{-1}A^T = I, \quad (1)$$

where  $I$  is the IDENTITY MATRIX. Written explicitly,

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}. \quad (2)$$

The symmetric part of any MATRIX may be obtained from

$$A_s = \frac{1}{2}(A + A^T). \quad (3)$$

A MATRIX  $A$  is symmetric if it can be expressed in the form

$$A = QDQ^T, \quad (4)$$

where  $Q$  is an ORTHOGONAL MATRIX and  $D$  is a DIAGONAL MATRIX. This is equivalent to the MATRIX equation

$$AQ = QD, \quad (5)$$

which is equivalent to

$$AQ_n = \lambda_n Q_n \quad (6)$$

for all  $n$ , where  $\lambda_n = D_{nn}$ . Therefore, the diagonal elements of  $D$  are the EIGENVALUES of  $A$ , and the columns of  $Q$  are the corresponding EIGENVECTORS.

see also ANTISYMMETRIC MATRIX, SKEW SYMMETRIC MATRIX

#### References

- Nash, J. C. "Real Symmetric Matrices." Ch. 10 in *Compact Numerical Methods for Computers: Linear Algebra and Function Minimisation*, 2nd ed. Bristol, England: Adam Hilger, pp. 119–134, 1990.

### Symmetric Points

Two points  $z$  and  $z^S \in \mathbb{C}^*$  are symmetric with respect to a CIRCLE or straight LINE  $L$  if all CIRCLES and straight LINES passing through  $z$  and  $z^S$  are orthogonal to  $L$ . MÖBIUS TRANSFORMATIONS preserve symmetry. Let a straight line be given by a point  $z_0$  and a unit VECTOR  $e^{i\theta}$ , then

$$z^S = e^{2i\theta}(z - z_0)^* + z_0.$$

Let a CIRCLE be given by center  $z_0$  and RADIUS  $r$ , then

$$z^S = z_0 + \frac{r^2}{(z - z_0)^*}.$$

see also MÖBIUS TRANSFORMATION

### Symmetric Relation

A RELATION  $R$  on a SET  $S$  is symmetric provided that for every  $x$  and  $y$  in  $S$  we have  $xRy$  IFF  $yRx$ .

see also RELATION

### Symmetric Tensor

A second-RANK symmetric TENSOR is defined as a TENSOR  $A$  for which

$$A^{mn} = A^{nm}. \quad (1)$$

Any TENSOR can be written as a sum of symmetric and ANTISYMMETRIC parts

$$\begin{aligned} A^{mn} &= \frac{1}{2}(A^{mn} + A^{nm}) + \frac{1}{2}(A^{mn} - A^{nm}) \\ &= \frac{1}{2}(B_S^{mn} + B_A^{mn}). \end{aligned} \quad (2)$$

The symmetric part of a TENSOR is denoted by parentheses as follows:

$$T_{(a,b)} \equiv \frac{1}{2}(T_{ab} + T_{ba}) \quad (3)$$

$$T_{(a_1, a_2, \dots, a_n)} \equiv \frac{1}{n!} \sum_{\text{permutations}} T_{a_1 a_2 \dots a_n}. \quad (4)$$

The product of a symmetric and an ANTISYMMETRIC TENSOR is 0. This can be seen as follows. Let  $a^{\alpha\beta}$  be ANTISYMMETRIC, so

$$a^{11} = a^{22} = 0 \quad (5)$$

$$a^{21} = -a^{12}. \quad (6)$$

Let  $b_{\alpha\beta}$  be symmetric, so

$$b_{12} = b_{21}. \quad (7)$$

Then

$$\begin{aligned} a^{\alpha\beta} b_{\alpha\beta} &= a^{11} b_{11} + a^{12} b_{12} + a^{21} b_{21} + a^{22} b_{22} \\ &= 0 + a^{12} b_{12} - a^{12} b_{12} + 0 = 0. \end{aligned} \quad (8)$$

A symmetric second-RANK TENSOR  $A_{mn}$  has SCALAR invariants

$$s_1 = A_{11} + A_{22} + A_{33} \quad (9)$$

$$\begin{aligned} s_2 &= A_{22} A_{33} + A_{33} A_{11} + A_{11} A_{22} - A_{23}^2 \\ &\quad - A_{31}^2 - A_{12}^2. \end{aligned} \quad (10)$$

## Symmetroid

A QUARTIC SURFACE which is the locus of zeros of the DETERMINANT of a SYMMETRIC  $4 \times 4$  matrix of linear forms. A general symmetroid has 10 ORDINARY DOUBLE POINTS (Jessop 1916, Hunt 1996).

## Symmetry

An intrinsic property of a mathematical object which causes it to remain invariant under certain classes of transformations (such as ROTATION, REFLECTION, INVERSION, or more abstract operations). The mathematical study of symmetry is systematized and formalized in the extremely powerful and beautiful AREA of mathematics called GROUP THEORY.

Symmetry can be present in the form of coefficients of equations as well as in the physical arrangement of objects. By classifying the symmetry of polynomial equations using the machinery of GROUP THEORY, for example, it is possible to prove the unsolvability of the general QUINTIC EQUATION.

In physics, an extremely powerful theorem of Noether states that each symmetry of a system leads to a physically conserved quantity. Symmetry under TRANSLATION corresponds to momentum conservation, symmetry under ROTATION to angular momentum conservation, symmetry in time to energy conservation, etc.

see also GROUP THEORY

## Symmetry Group

see GROUP

## Symmetry Operation

Symmetry operations include the IMPROPER ROTATION, INVERSION OPERATION, MIRROR PLANE, and ROTATION. Together, these operations create 32 crystal classes corresponding to the 32 POINT GROUPS.

The INVERSION OPERATION takes

$$(x, y, z) \rightarrow (-x, -y, -z)$$

and is denoted  $i$ . When used in conjunction with a ROTATION, it becomes an IMPROPER ROTATION. An IMPROPER ROTATION by  $360^\circ/n$  is denoted  $\bar{n}$  (or  $S_n$ ). For periodic crystals, the CRYSTALLOGRAPHY RESTRICTION allows only the IMPROPER ROTATIONS  $\bar{1}$ ,  $\bar{2}$ ,  $\bar{3}$ ,  $\bar{4}$ , and  $\bar{6}$ .

The MIRROR PLANE symmetry operation takes

$$(x, y, z) \rightarrow (x, y, -z), (x, -y, z) \rightarrow (x, -y, z),$$

etc., which is equivalent to  $\bar{2}$ . Invariance under reflection can be denoted  $n\sigma_v$  or  $n\sigma_h$ . The ROTATION symmetry operation for  $360^\circ/n$  is denoted  $n$  (or  $C_n$ ). For periodic crystals, CRYSTALLOGRAPHY RESTRICTION allows only 1, 2, 3, 4, and 6.

Symmetry operations can be indicated with symbols such as  $C_n$ ,  $S_n$ ,  $E$ ,  $i$ ,  $n\sigma_v$ , and  $n\sigma_h$ .

1.  $C_n$  indicates ROTATION about an  $n$ -fold symmetry axis.
2.  $S_n$  indicates IMPROPER ROTATION about an  $n$ -fold symmetry axis.
3.  $E$  (or  $I$ ) indicates invariance under TRANSLATION.
4.  $i$  indicates a center of symmetry under INVERSION.

5.  $n\sigma_v$  indicates invariance under  $n$  vertical REFLECTIONS.
6.  $n\sigma_h$  indicates invariance under  $n$  horizontal REFLECTIONS.

see also CRYSTALLOGRAPHY RESTRICTION, IMPROPER ROTATION, INVERSION OPERATION, MIRROR PLANE, POINT GROUPS, ROTATION, SYMMETRY

### Symmetry Principle

SYMMETRIC POINTS are preserved under a MÖBIUS TRANSFORMATION.

see also MÖBIUS TRANSFORMATION, SYMMETRIC POINTS

### Symplectic Diffeomorphism

A MAP  $T : (M_1, \omega_1) \rightarrow (M_2, \omega_2)$  between the SYMPLECTIC MANIFOLDS  $(M_1, \omega_1)$  and  $(M_2, \omega_2)$  which is a DIFFEOMORPHISM and  $T^*(\omega_2) = \omega_1$  (where  $T^*$  is the PULLBACK MAP induced by  $T$ , i.e., the derivative of the DIFFEOMORPHISM  $T$  acting on tangent vectors). A symplectic diffeomorphism is also known as a SYMPLECTOMORPHISM or CANONICAL TRANSFORMATION.

see also DIFFEOMORPHISM, PULLBACK MAP, SYMPLECTIC MANIFOLD

#### References

Guillemin, V. and Sternberg, S. *Symplectic Techniques in Physics*. New York: Cambridge University Press, p. 34, 1984.

### Symplectic Form

A symplectic form on a SMOOTH MANIFOLD  $M$  is a smooth closed 2-FORM  $\omega$  on  $M$  which is nondegenerate such that at every point  $m$ , the alternating bilinear form  $\omega_m$  on the TANGENT SPACE  $T_m M$  is nondegenerate.

A symplectic form on a VECTOR SPACE  $V$  over  $F_q$  is a function  $f(x, y)$  (defined for all  $x, y \in V$  and taking values in  $F_q$ ) which satisfies

$$f(\lambda_1 x_1 + \lambda_2 x_2, y) = \lambda_1 f(x_1, y) + \lambda_2 f(x_2, y),$$

$$f(y, x) = -f(x, y),$$

and

$$f(x, x) = 0.$$

Symplectic forms can exist on  $M$  (or  $V$ ) only if  $M$  (or  $V$ ) is EVEN-dimensional.

### Symplectic Group

The symplectic group  $Sp_n(q)$  for  $n$  EVEN is the GROUP of elements of the GENERAL LINEAR GROUP  $GL_n$  that preserve a given nonsingular SYMPLECTIC FORM. Any such MATRIX has DETERMINANT 1.

see also GENERAL LINEAR GROUP, LIE-TYPE GROUP, PROJECTIVE SYMPLECTIC GROUP, SYMPLECTIC FORM

#### References

Wilson, R. A. "ATLAS of Finite Group Representation." <http://for.mat.bham.ac.uk/atlas#symp>.

### Symplectic Manifold

A pair  $(M, \omega)$ , where  $M$  is a MANIFOLD and  $\omega$  is a SYMPLECTIC FORM on  $M$ . The PHASE SPACE  $\mathbb{R}^{2n} = \mathbb{R}^n \times \mathbb{R}^n$  is a symplectic manifold. Near every point on a symplectic manifold, it is possible to find a set of local "Darboux coordinates" in which the SYMPLECTIC FORM has the simple form

$$\omega = \sum_k dq_k \wedge dp_k$$

(Sjamaar 1996), where  $dq_k \wedge dp_k$  is a WEDGE PRODUCT.

see also MANIFOLD, SYMPLECTIC DIFFEOMORPHISM, SYMPLECTIC FORM

### Symplectic Map

A MAP which preserves the sum of AREAS projected onto the set of  $(p_i, q_i)$  planes. It is the generalization of an AREA-PRESERVING MAP.

see also AREA-PRESERVING MAP, LIOUVILLE'S PHASE SPACE THEOREM

### Symplectomorphism

see SYMPLECTIC DIFFEOMORPHISM

### Synclastic

A surface on which the GAUSSIAN CURVATURE  $K$  is everywhere POSITIVE. When  $K$  is everywhere NEGATIVE, a surface is called ANTICLASTIC. A point at which the GAUSSIAN CURVATURE is POSITIVE is called an ELLIPTIC POINT.

see also ANTICLASTIC, ELLIPTIC POINT, GAUSSIAN QUADRATURE, HYPERBOLIC POINT, PARABOLIC POINT, PLANAR POINT

### Synergetics

Synergetics deals with systems composed of many subsystems which may each be of a very different nature. In particular, synergetics treats systems in which co-operation among subsystems creates organized structure on macroscopic scales (Haken 1993). Examples of problems treated by synergetics include BIFURCATIONS, phase transitions in physics, convective instabilities, coherent oscillations in lasers, nonlinear oscillations in electrical circuits, population dynamics, etc.

see also BIFURCATION, CHAOS, DYNAMICAL SYSTEM

### System of Equations

Let a linear system of equations be denoted

$$\mathbf{AX} = \mathbf{Y}, \quad (1)$$

where  $\mathbf{A}$  is a MATRIX and  $\mathbf{X}$  and  $\mathbf{Y}$  are VECTORS. As shown by CRAMER'S RULE, there is a unique solution if  $\mathbf{A}$  has a MATRIX INVERSE  $\mathbf{A}^{-1}$ . In this case,

$$\mathbf{X} = \mathbf{A}^{-1}\mathbf{Y}. \quad (2)$$

If  $\mathbf{Y} = \mathbf{0}$ , then the solution is  $\mathbf{X} = \mathbf{0}$ . If  $\mathbf{A}$  has no MATRIX INVERSE, then the solution SUBSPACE is either a LINE or the EMPTY SET. If two equations are multiples of each other, solutions are of the form

$$\mathbf{X} = \mathbf{A} + t\mathbf{B}, \quad (3)$$

for  $t$  a REAL NUMBER.

see also CRAMER'S RULE, MATRIX INVERSE

### Syzygies Problem

The problem of finding all independent irreducible algebraic relations among any finite set of QUANTICS.

see also QUANTIC

### Syzygy

A technical mathematical object defined in terms of a POLYNOMIAL RING of  $n$  variables over a FIELD  $k$ .

### Szilassi Polyhedron

A POLYHEDRON which is topologically equivalent to a TORUS and for which every pair of faces has an EDGE in common. This polyhedron was discovered by L. Szilassi in 1977. Its SKELETON is equivalent to the seven-color torus map illustrated below.

The Szilassi polyhedron has 14 VERTICES, seven faces, and 21 EDGES, and is the DUAL POLYHEDRON of the CSÁSZÁR POLYHEDRON.

## Tait Flying Conjecture

see FLYING CONJECTURE

**Tait's Hamiltonian Graph Conjecture**

Every 3-connected cubic GRAPH (each VERTEX has VALENCY 3) has a HAMILTONIAN CIRCUIT. Proposed by Tait in 1880 and refuted by W. T. Tutte in 1946 with a counterexample, TUTTE'S GRAPH. If it had been true, it would have implied the FOUR-COLOR THEOREM. A simpler counterexample was later given by Kozyrev and Grinberg.

see also HAMILTONIAN CIRCUIT, TUTTE'S GRAPH, VERTEX (GRAPH)

**References**

Honsberger, R. *Mathematical Gems I*. Washington, DC: Math. Assoc. Amer., pp. 82–89, 1973.

**Tait's Knot Conjectures**

P. G. Tait undertook a study of KNOTS in response to Kelvin's conjecture that the atoms were composed of knotted vortex tubes of ether (Thomson 1869). He categorized KNOTS in terms of the number of crossings in a plane projection. He also made some conjectures which remained unproven until the discovery of JONES POLYNOMIALS.

Tait's FLYPING CONJECTURE states that the number of crossings is the same for any diagram of an ALTERNATING KNOT. This was proved true in 1986.

**TAK Function**

A RECURSIVE FUNCTION devised by I. Takeuchi. For INTEGERS  $x$ ,  $y$ , and  $z$ , and a function  $h$ , it is

$TAK_h(x, y, z)$

$$= \begin{cases} h(x, y, z) & \text{for } x \leq y \\ h(h(x-1, y, z), h(y-1, z, x)), & \text{for } x > y. \\ h(z-1, x, y) \end{cases}$$

The number of function calls  $F_0(a, b)$  required to compute  $TAK_0(a, b, 0)$  for  $a > b > 0$  is

$$\begin{aligned} F_0(a, b) &= 4 \sum_{k=0}^b \frac{a-b}{a+b-2k} \left( \frac{a+b-2k}{b-k} \right) - 3 \\ &= 1 + 4 \sum_{k=0}^{b-1} \frac{a-b}{a+b-2k} \left( \frac{a+b-2k}{b-k} \right) \end{aligned}$$

(Vardi 1991).

The TAK function is also connected with the BALLOT PROBLEM (Vardi 1991).

An  $n \times n$  ARRAY of the integers from 1 to  $n^2$  such that the difference between any one integer and its neighbor (horizontally, vertically, or diagonally, without wrapping around) is greater than or equal to some value  $k$  is called a  $(n, k)$ -talisman square. The above illustrations show (4, 2)-, (4, 3)-, (5, 4)-, and (6, 8)-talisman squares.

### Tame Algebra

Let  $A$  denote an  $\mathbb{R}$ -algebra, so that  $A$  is a VECTOR SPACE over  $\mathbb{R}$  and

$$A \times A \rightarrow A$$

$$(x, y) \mapsto x \cdot y,$$

where  $x \cdot y$  is vector multiplication which is assumed to be BILINEAR. Now define

$$Z \equiv \{x \in A : x \cdot y = 0 \text{ for some nonzero } y \in A\},$$

where  $0 \in Z$ .  $A$  is said to be tame if  $Z$  is a finite union of SUBSPACES of  $A$ . A 2-D 0-ASSOCIATIVE algebra is

tame, but a 4-D 4-ASSOCIATIVE algebra and a 3-D 1-ASSOCIATIVE algebra need not be tame. It is conjectured that a 3-D 2-ASSOCIATIVE algebra is tame, and proven that a 3-D 3-ASSOCIATIVE algebra is tame if it possesses a multiplicative IDENTITY ELEMENT.

### Tangency Theorem

The external (internal) SIMILARITY POINT of two fixed CIRCLES is the point at which all the CIRCLES homogeneously (nonhomogeneously) tangent to the fixed CIRCLES have the same POWER and at which all the tangency secants intersect.

#### References

Dörrie, H. *100 Great Problems of Elementary Mathematics: Their History and Solutions*. New York: Dover, p. 157, 1965.

### Tangent

The tangent function is defined by

$$\tan \theta \equiv \frac{\sin \theta}{\cos \theta}, \quad (1)$$

where  $\sin x$  is the SINE function and  $\cos x$  is the COSINE function. The word "tangent," however, also has an important related meaning as a LINE or PLANE which touches a given curve or solid at a single point. These geometrical objects are then called a TANGENT LINE or TANGENT PLANE, respectively.

The MACLAURIN SERIES for the tangent function is

$$\tan x = \sum \frac{(-1)^{n-1} 2^{2n} (2^{2n} - 1) B_{2n}}{(2n)!} x^{2n-1} + \dots$$

$$= x + \frac{1}{3}x^3 + \frac{2}{15}x^5 + \frac{17}{315}x^7 + \frac{62}{2835}x^9 + \dots, \quad (2)$$

where  $B_n$  is a BERNOULLI NUMBER.

$\tan x$  is IRRATIONAL for any RATIONAL  $x \neq 0$ , which can be proved by writing  $\tan x$  as a CONTINUED FRACTION

$$\tan x = \frac{x}{1 - \frac{x^2}{3 - \frac{x^2}{5 - \frac{x^2}{7 - \dots}}}}. \quad (3)$$

Lambert derived another CONTINUED FRACTION expression for the tangent,

$$\tan x = \frac{1}{\frac{1}{x} - \frac{1}{\frac{3}{x} - \frac{1}{\frac{5}{x} - \frac{1}{\frac{7}{x} - \dots}}}}}. \quad (4)$$

An interesting identity involving the PRODUCT of tangents is

$$\prod_{k=1}^{[(n-1)/2]} \tan\left(\frac{k\pi}{n}\right) = \begin{cases} \sqrt{n} & \text{for } n \text{ odd} \\ 1 & \text{for } n \text{ even,} \end{cases} \quad (5)$$

where  $[x]$  is the FLOOR FUNCTION. Another tangent identity is

$$\tan(n \tan^{-1} x) = \frac{1}{i} \frac{(1+ix)^n - (1-ix)^n}{(1+ix)^n + (1-ix)^n} \quad (6)$$

(Beeler *et al.* 1972, Item 16).

#### Tangent Bifurcation

see FOLD BIFURCATION

#### Tangent Bundle

The tangent bundle  $TM$  of a SMOOTH MANIFOLD  $M$  is the SPACE of TANGENT VECTORS to points in the manifold, i.e., it is the set  $(x, v)$  where  $x \in M$  and  $v$  is tangent to  $x \in M$ . For example, the tangent bundle to the CIRCLE is the CYLINDER.

see also COTANGENT BUNDLE, TANGENT VECTOR

#### Tangent Developable

A RULED SURFACE  $M$  is a tangent developable of a curve  $y$  if  $M$  can be parameterized by  $\mathbf{x}(u, v) = \mathbf{y}(u) + v\mathbf{y}'(u)$ . A tangent developable is a FLAT SURFACE.

### Tangent Map

If  $f : M \rightarrow N$ , then the tangent map  $Tf$  associated to  $f$  is a VECTOR BUNDLE HOMEOMORPHISM  $Tf : TM \rightarrow TN$  (i.e., a MAP between the TANGENT BUNDLES of  $M$  and  $N$  respectively). The tangent map corresponds to DIFFERENTIATION by the formula

$$Tf(v) = (f \circ \phi)'(0), \quad (1)$$

where  $\phi'(0) = v$  (i.e.,  $\phi$  is a curve passing through the base point to  $v$  in  $TM$  at time 0 with velocity  $v$ ). In this case, if  $f : M \rightarrow N$  and  $g : N \rightarrow O$ , then the CHAIN RULE is expressed as

$$T(f \circ g) = Tf \circ Tg. \quad (2)$$

In other words, with this way of formalizing differentiation, the CHAIN RULE can be remembered by saying that "the process of taking the tangent map of a map is functorial." To a topologist, the form

$$(f \circ g)'(a) = f'(g(a)) \circ g'(a), \quad (3)$$

for all  $a$ , is more intuitive than the usual form of the CHAIN RULE.

### Tangent Plane

A tangent plane is a PLANE which meets a given SURFACE at a single POINT. Let  $(x_0, y_0)$  be any point of a surface function  $z = f(x, y)$ . The surface has a nonvertical tangent plane at  $(x_0, y_0)$  with equation

$$z = f(x_0, y_0) + f_x(x_0, y_0)(x - x_0) + f_y(x_0, y_0)(y - y_0).$$

see also NORMAL VECTOR, TANGENT, TANGENT LINE, TANGENT SPACE, TANGENT VECTOR

### Tangent Space

Let  $x$  be a point in an  $n$ -dimensional COMPACT MANIFOLD  $M$ , and attach at  $x$  a copy of  $\mathbb{R}^n$  tangential to  $M$ . The resulting structure is called the TANGENT SPACE of  $M$  at  $x$  and is denoted  $T_x M$ . If  $\gamma$  is a smooth curve passing through  $x$ , then the derivative of  $\gamma$  at  $x$  is a VECTOR in  $T_x M$ .

see also TANGENT, TANGENT BUNDLE, TANGENT PLANE, TANGENT VECTOR

### Tangent Vector

For a curve with POSITION VECTOR  $\mathbf{r}(t)$ , the unit tangent vector  $\hat{\mathbf{T}}(t)$  is defined by

$$\hat{\mathbf{T}}(t) \equiv \frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \frac{\frac{d\mathbf{r}}{dt}}{\left| \frac{d\mathbf{r}}{dt} \right|} \quad (1)$$

$$= \frac{\frac{d\mathbf{r}}{dt}}{\frac{ds}{dt}} \quad (2)$$

$$= \frac{d\mathbf{r}}{ds}, \quad (3)$$

where  $t$  is a parameterization variable and  $s$  is the ARC LENGTH. For a function given parametrically by  $(f(t), g(t))$ , the tangent vector relative to the point  $(f(t), g(t))$  is therefore given by

$$x(t) = \frac{f'}{\sqrt{f'^2 + g'^2}} \quad (4)$$

$$y(t) = \frac{g'}{\sqrt{f'^2 + g'^2}}. \quad (5)$$

To actually place the vector tangent to the curve, it must be displaced by  $(f(t), g(t))$ . It is also true that

$$\frac{d\hat{\mathbf{T}}}{ds} = \kappa \hat{\mathbf{N}} \quad (6)$$

$$\frac{d\hat{\mathbf{T}}}{dt} = \kappa \frac{ds}{dt} \hat{\mathbf{N}} \quad (7)$$

$$[\hat{\mathbf{T}}, \ddot{\mathbf{T}}, \ddot{\ddot{\mathbf{T}}}] = \kappa^5 \frac{d}{ds} \left( \frac{\tau}{\kappa} \right), \quad (8)$$

where  $\mathbf{N}$  is the NORMAL VECTOR,  $\kappa$  is the CURVATURE, and  $\tau$  is the TORSION.

### References

Gray, A. "Tangent and Normal Lines to Plane Curves." §5.5 in *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 85–90, 1993.

**Tangential Angle**

For a PLANE CURVE, the tangential angle  $\phi$  is defined by

$$\rho d\phi = ds, \quad (1)$$

where  $s$  is the ARC LENGTH and  $\rho$  is the RADIUS OF CURVATURE. The tangential angle is therefore given by

$$\phi = \int_0^t s'(t)\kappa(t) dt, \quad (2)$$

where  $\kappa(t)$  is the CURVATURE. For a plane curve  $\mathbf{r}(t)$ , the tangential angle  $\phi(t)$  can also be defined by

$$\frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \begin{bmatrix} \cos[\phi(t)] \\ \sin[\phi(t)] \end{bmatrix}. \quad (3)$$

Gray (1993) calls  $\phi$  the TURNING ANGLE instead of the tangential angle.

**Tangents Law**

see LAW OF TANGENTS

**Tangle**

A region in a KNOT or LINK projection plane surrounded by a CIRCLE such that the KNOT or LINK crosses the circle exactly four times. Two tangles are equivalent if a sequence of REIDEMEISTER MOVES can be used to transform one into the other while keeping the four string endpoints fixed and not allowing strings to pass outside the CIRCLE.

The simplest tangles are the  $\infty$ -tangle and 0-tangle, shown above. A tangle with  $n$  left-handed twists is called an  $n$ -tangle, and one with  $n$  right-handed twists is called a  $-n$ -tangle. By placing tangles side by side, more complicated tangles can be built up such as  $(-2, 3, 2)$ , etc. The link created by connecting the ends of the tangles is now described by the sequence of tangle symbols, known as CONWAY'S KNOT NOTATION. If tangles are multiplied by 0 and then added, the resulting tangle symbols are separated by commas. Additional symbols which are used are the period, colon, and asterisk.

Amazingly enough, two tangles described in this NOTATION are equivalent IFF the CONTINUED FRACTIONS of the form

$$2 + \frac{1}{3 + \frac{1}{-2}}$$

are equal (Burde and Zieschang 1985)! An ALGEBRAIC TANGLE is any tangle obtained by ADDITIONS and MULTIPLICATIONS of rational tangles (Adams 1994). Not all tangles are ALGEBRAIC.

## Tanh

see HYPERBOLIC TANGENT

## Taniyama Conjecture

see TANIYAMA-SHIMURA CONJECTURE

## Taniyama-Shimura Conjecture

A conjecture which arose from several problems proposed by Taniyama in an international mathematics symposium in 1955. Let  $E$  be an ELLIPTIC CURVE whose equation has INTEGER COEFFICIENTS, let  $N$  be the CONDUCTOR of  $E$  and, for each  $n$ , let  $a_n$  be the number appearing in the  $L$ -function of  $E$ . Then there exists a MODULAR FORM of weight two and level  $N$  which is an eigenform under the HECKE OPERATORS and has a FOURIER SERIES  $\sum a_n q^n$ .

The conjecture says, in effect, that every rational ELLIPTIC CURVE is a MODULAR FORM in disguise. Stated formally, the conjecture suggests that, for every ELLIPTIC CURVE  $y^2 = Ax^3 + Bx^2 + Cx + D$  over the RATIONALS, there exist nonconstant MODULAR FUNCTIONS  $f(z)$  and  $g(z)$  of the same level  $N$  such that

$$[f(z)]^2 = A[g(z)]^2 + Cg(z) + D.$$

Equivalently, for every ELLIPTIC CURVE, there is a MODULAR FORM with the same DIRICHLET  $L$ -SERIES.

In 1985, starting with a fictitious solution to FERMAT'S LAST THEOREM, G. Frey showed that he could create an unusual ELLIPTIC CURVE which appeared not to be modular. If the curve were not modular, then this would show that if FERMAT'S LAST THEOREM were false, then the Taniyama-Shimura conjecture would also be false. Furthermore, if the Taniyama-Shimura conjecture were true, then so would be FERMAT'S LAST THEOREM!

However, Frey did not actually prove whether his curve was modular. The conjecture that Frey's curve was modular came to be called the "epsilon conjecture," and was quickly proved by Ribet (RIBET'S THEOREM) in 1986, establishing a very close link between two mathematical structures (the Taniyama-Shimura conjecture and FERMAT'S LAST THEOREM) which appeared previously to be completely unrelated.

As of the early 1990s, most mathematicians believed that the Taniyama-Shimura conjecture was not accessible to proof. However, A. Wiles was not one of these. He attempted to establish the correspondence between the set of ELLIPTIC CURVES and the set of modular elliptic curves by showing that the number of each was the same. Wiles accomplished this by "counting" Galois representations and comparing them with the number of modular forms. In 1993, after a monumental seven-year effort, Wiles (almost) proved the Taniyama-Shimura conjecture for special classes of curves called SEMISTABLE ELLIPTIC CURVES.

Wiles had tried to use horizontal Iwasawa theory to create a so-called CLASS NUMBER formula, but was initially unsuccessful and therefore used instead an extension of a result of Flach based on ideas from Kolyvagin. However, there was a problem with this extension which was discovered during review of Wiles' manuscript in September 1993. Former student Richard Taylor came to Princeton in early 1994 to help Wiles patch up this error. After additional effort, Wiles discovered the reason that the Flach/Kolyvagin approach was failing, and also discovered that it was precisely what had prevented Iwasawa theory from working.

With this additional insight, he was able to successfully complete the erroneous portion of the proof using Iwasawa theory, proving the SEMISTABLE case of the Taniyama-Shimura conjecture (Taylor and Wiles 1995, Wiles 1995) and, at the same time, establishing FERMAT'S LAST THEOREM as a true theorem.

#### Tau Conjecture

Also known as RAMANUJAN'S HYPOTHESIS. Ramanujan proposed that

$$\tau(n) \sim \mathcal{O}(n^{11/2+\epsilon}),$$

where  $\tau(n)$  is the TAU FUNCTION, defined by

$$\sum_{n=1}^{\infty} \tau(n)x^n = x(1 - 3x + 5x^3 - 7x^6 + \dots)^8.$$

This was proven by Deligne (1974), who was subsequently awarded the FIELDS MEDAL for his proof.

see also TAU FUNCTION

## Tau Function

A function  $\tau(n)$  related to the DIVISOR FUNCTION  $\sigma_k(n)$ , also sometimes called RAMANUJAN'S TAU FUNCTION. It is given by the GENERATING FUNCTION

$$\sum_{n=1}^{\infty} \tau(n)x^n = \prod_{n=1}^{\infty} (1 - x^n)^{24}, \quad (1)$$

and the first few values are 1, -24, 252, -1472, 4380, ... (Sloane's A000594).  $\tau(n)$  is also given by

$$g(-x) = \sum_{n=1}^{\infty} (-1)^n \tau(n)x^n \quad (2)$$

$$g(x^2) = \sum_{n=1}^{\infty} \tau\left(\frac{1}{2}n\right)x^n \quad (3)$$

$$\sum_{n=1}^{\infty} \tau(n)x^n = x(1 - 3x + 5x^3 - 7x^6 + \dots)^8. \quad (4)$$

In ORE'S CONJECTURE, the tau function appears as the number of DIVISORS of  $n$ . Ramanujan conjectured and Mordell proved that if  $(n, n')$ , then

$$\tau(nn') = \tau(n)\tau(n'). \quad (5)$$

Ramanujan conjectured and Watson proved that  $\tau(n)$  is divisible by 691 for almost all  $n$ . If

$$\tau(p) \equiv 0 \pmod{p}, \quad (6)$$

then

$$\tau(pn) \equiv 0 \pmod{p}. \quad (7)$$

Values of  $p$  for which the first equation holds are  $p = 2, 3, 5, 7, 23$ .

Ramanujan also studied

$$f(x) \equiv \sum_{n=1}^{\infty} \tau(n)n^{-s}, \quad (8)$$

which has properties analogous to the RIEMANN ZETA FUNCTION. It satisfies

$$\frac{f(s)\Gamma(s)}{(2\pi)^s} = \frac{f(12-s)}{(2\pi)^{12-s}}, \quad (9)$$

and Ramanujan's TAU-DIRICHLET SERIES conjecture alleges that all nontrivial zeros of  $f(s)$  lie on the line  $\Re[s] = 6$ .  $f$  can be split up into

$$f(6+it) = z(t)e^{-i\theta(t)}, \quad (10)$$

where

$$z(t) = \Gamma(6+it)f(6+it)(2\pi)^{-it} \times \sqrt{\frac{\sinh(\pi t)}{\pi t(1+t^2)(4+t^2)(9+t^2)(16+t^2)(25+t^2)}} \quad (11)$$

$$\theta(t) = -\frac{1}{2}i \ln \left[ \frac{\Gamma(6+it)}{\Gamma(6-it)} \right] - t \ln(2\pi). \quad (12)$$

The SUMMATORY tau function is given by

$$T(n) = \sum'_{n \leq x} \tau(n). \quad (13)$$

Here, the prime indicates that when  $x$  is an INTEGER, the last term  $\tau(x)$  should be replaced by  $\frac{1}{2}\tau(x)$ .

Ramanujan's tau theta function  $Z(t)$  is a REAL function for REAL  $t$  and is analogous to the RIEMANN-SIEGEL FUNCTION  $Z$ . The number of zeros in the critical strip from  $t = 0$  to  $T$  is given by

$$N(t) = \frac{\Theta(T) + \Im\{\ln[\tau_{DS}(6+iT)]\}}{\pi}, \quad (14)$$

where  $\Theta$  is the RIEMANN THETA FUNCTION and  $\tau_{DS}$  is the TAU-DIRICHLET SERIES, defined by

$$\tau_{DS}(s) \equiv \sum_{n=1}^{\infty} \frac{\tau(n)}{n^s}. \quad (15)$$

Ramanujan conjectured that the nontrivial zeros of the function are all real.

Ramanujan's  $\tau_z$  function is defined by

$$\tau_z(t) = \frac{\Gamma(6+it)(2\pi)^{-it}}{\tau_{DS}(6+it) \sqrt{\frac{\sinh(\pi t)}{\pi t \prod_{k=1}^5 k^2+t^2}}}, \quad (16)$$

where  $\tau_{DS}(z)$  is the TAU-DIRICHLET SERIES.

#### Tauberian Theorem

A Tauberian theorem is a theorem which deduces the convergence of an INFINITE SERIES on the basis of the properties of the function it defines and any kind of auxiliary HYPOTHESIS which prevents the general term of the series from converging to zero too slowly.

see also HARDY-LITTLEWOOD TAUBERIAN THEOREM

#### Tautochrone Problem

Find the curve down which a bead placed anywhere will fall to the bottom in the same amount of time. The solution is a CYCLOID, a fact first discovered and published by Huygens in *Horologium oscillatorium* (1673). Huygens also constructed the first pendulum clock with a device to ensure that the pendulum was isochronous by forcing the pendulum to swing in an arc of a CYCLOID.

The parametric equations of the CYCLOID are

$$x = a(\theta - \sin \theta) \quad (1)$$

$$y = a(1 - \cos \theta). \quad (2)$$

To see that the CYCLOID satisfies the tautochrone property, consider the derivatives

$$x' = a(1 - \cos \theta) \quad (3)$$

$$y' = a \sin \theta, \quad (4)$$

and

$$\begin{aligned} x'^2 + y'^2 &= a^2[(1 - 2\cos \theta + \cos^2 \theta) + \sin^2 \theta] \\ &= 2a^2(1 - \cos \theta). \end{aligned} \quad (5)$$

Now

$$\frac{1}{2}mv^2 = mgy \quad (6)$$

$$v = \frac{ds}{dt} = \sqrt{2gy} \quad (7)$$

$$\begin{aligned} dt &= \frac{ds}{\sqrt{2gy}} = \frac{\sqrt{dx^2 + dy^2}}{\sqrt{2gy}} \\ &= \frac{a\sqrt{2(1 - \cos \theta)} d\theta}{\sqrt{2ga(1 - \cos \theta)}} = \sqrt{\frac{a}{g}} d\theta, \end{aligned} \quad (8)$$

so the time required to travel from the top of the CYCLOID to the bottom is

$$T = \int_0^\pi dt = \sqrt{\frac{a}{g}} \pi. \quad (9)$$

However, from an intermediate point  $\theta_0$ ,

$$v = \frac{ds}{dt} = \sqrt{2g(y - y_0)}, \quad (10)$$

so

$$\begin{aligned} T &= \int_{\theta_0}^\pi \frac{\sqrt{2a^2(1 - \cos \theta)}}{2ag(\cos \theta_0 - \cos \theta)} d\theta \\ &= \sqrt{\frac{a}{g}} \int_{\theta_0}^\pi \sqrt{\frac{1 - \cos \theta}{\cos \theta_0 - \cos \theta}} d\theta \\ &= \sqrt{\frac{a}{g}} \int_{\theta_0}^\pi \frac{\sin(\frac{1}{2}\theta) d\theta}{\sqrt{\cos^2(\frac{1}{2}\theta_0) - \cos^2(\frac{1}{2}\theta)}}. \end{aligned} \quad (11)$$

Now let

$$u = \frac{\cos(\frac{1}{2}\theta)}{\cos(\frac{1}{2}\theta_0)} \quad (12)$$

$$du = -\frac{\sin(\frac{1}{2}\theta)d\theta}{2\cos(\theta_0)}, \quad (13)$$

so

$$T = -2\sqrt{\frac{a}{g}} \int_1^0 \frac{du}{\sqrt{1-u^2}} = 2\sqrt{\frac{a}{g}} [\sin^{-1} u]_0^1 = \pi \sqrt{\frac{a}{g}}, \quad (14)$$

and the amount of time is the same from any point!

#### Tautology

A logical statement in which the conclusion is equivalent to the premise. If  $p$  is a tautology, it is written  $\models p$ .

**Taxicab Number**

The  $n$ th taxicab number  $Ta(n)$  is the smallest number representable in  $n$  ways as a sum of POSITIVE CUBES. The numbers derive their name from the HARDY-RAMANUJAN NUMBER

$$\begin{aligned} Ta(2) &= 1729 \\ &= 1^3 + 12^3 \\ &= 9^3 + 10^3, \end{aligned} \quad (1)$$

which is associated with the following story told about Ramanujan by G. H. Hardy. "Once, in the taxi from London, Hardy noticed its number, 1729. He must have thought about it a little because he entered the room where Ramanujan lay in bed and, with scarcely a hello, blurted out his disappointment with it. It was, he declared, 'rather a dull number,' adding that he hoped that wasn't a bad omen. 'No, Hardy,' said Ramanujan, 'it is a very interesting number. It is the smallest number expressible as the sum of two [POSITIVE] cubes in two different ways'" (Hofstadter 1989, Kanigel 1991, Snow 1993).

However, this property was also known as early as 1657 by F. de Bessy (Berndt and Bhargava 1993, Guy 1994). Leech (1957) found

$$\begin{aligned} Ta(3) &= 87539319 \\ &= 167^3 + 436^3 \\ &= 228^3 + 423^3 \\ &= 255^3 + 414^3. \end{aligned} \quad (2)$$

Rosenstiel *et al.* (1991) recently found

$$\begin{aligned} Ta(4) &= 6963472309248 \\ &= 2421^3 + 19083^3 \\ &= 5436^3 + 18948^3 \\ &= 10200^3 + 18072^3 \\ &= 13322^3 + 16630^3. \end{aligned} \quad (3)$$

D. Wilson found

$$\begin{aligned} Ta(5) &= 48988659276962496 \\ &= 38787^3 + 365757^3 \\ &= 107839^3 + 362753^3 \\ &= 205292^3 + 342952^3 \\ &= 221424^3 + 336588^3 \\ &= 231518^3 + 331954^3. \end{aligned} \quad (4)$$

The first few taxicab numbers are therefore 2, 1729, 87539319, 6963472309248, ... (Sloane's A011541).

Hardy and Wright (Theorem 412, 1979) show that the number of such sums can be made arbitrarily large but, updating Guy (1994) with Wilson's result, the least example is not known for six or more equal sums.

Sloane defines a slightly different type of taxicab numbers, namely numbers which are sums of two cubes in two or more ways, the first few of which are 1729, 4104, 13832, 20683, 32832, 39312, 40033, 46683, 64232, ... (Sloane's A001235).

**Taylor's Condition**

For a given POSITIVE INTEGER  $n$ , does there exist a WEIGHTED TREE with  $n$  VERTICES whose paths have weights  $1, 2, \dots, \binom{n}{2}$ , where  $\binom{n}{2}$  is a BINOMIAL COEFFICIENT? Taylor showed that no such TREE can exist unless it is a PERFECT SQUARE or a PERFECT SQUARE plus 2. No such TREES are known except  $n = 2, 3, 4$ , and 6.

**Taylor Series**

A Taylor series is a series expansion of a FUNCTION about a point. A 1-D Taylor series is an expansion of a SCALAR FUNCTION  $f(x)$  about a point  $x = a$ . If  $a = 0$ , the expansion is known as a MACLAURIN SERIES.

$$\int_a^x f^{(n)}(x) dx = [f^{(n-1)}(x)]_a^x = f^{(n-1)}(x) - f^{(n-1)}(a) \quad (1)$$

$$\begin{aligned} \int_a^x \left[ \int_a^x f^{(n)}(x) dx \right] dx &= \int_a^x [f^{(n-1)}(x) - f^{(n-1)}(a)] dx \\ &= f^{(n-2)}(x) - f^{(n-2)}(a) - (x-a)f^{(n-1)}(a). \end{aligned} \quad (2)$$

Continuing,

$$\begin{aligned} \iiint_a^x f^{(n)}(x) (dx)^3 &= f^{(n-3)}(a) - (x-a)f^{(n-2)}(a) \\ &\quad - \frac{1}{2!}(x-a)^2 f^{(n-1)}(a) \end{aligned} \quad (3)$$

$$\begin{aligned} \underbrace{\int \cdots \int_a^x}_{n} f^{(n)}(x) (dx)^n &= f(x) - f(a) - (x-a)f'(a) \\ &\quad - \frac{1}{2!}(x-a)^2 f''(a) - \cdots - \frac{1}{(n-1)!}(x-a)^{n-1} f^{(n-1)}(a). \end{aligned} \quad (4)$$

Therefore, we obtain the 1-D Taylor series

$$\begin{aligned} f(x) &= f(a) + (x-a)f'(a) + \frac{1}{2!}(x-a)^2 f''(a) + \cdots \\ &\quad + \frac{1}{(n-1)!}(x-a)^{n-1} f^{(n-1)}(a) + R_n, \end{aligned} \quad (5)$$

where  $R_n$  is a remainder term defined by

$$R_n = \underbrace{\int \cdots \int_a^x}_{n} f^{(n)}(x) (dx)^n. \quad (6)$$

Using the MEAN-VALUE THEOREM for a function  $g$ , it must be true that

$$\int_a^x g(x) dx = (x-a)g(x^*) \quad (7)$$

for some  $x^* \in [a, x]$ . Therefore, integrating  $n$  times gives the result

$$R_n = \frac{(x-a)^n}{n!} f^{(n)}(x^*). \quad (8)$$

The maximum error is then the maximum value of (8) for all possible  $x^* \in [a, x]$ .

An alternative form of the 1-D Taylor series may be obtained by letting

$$x - a \equiv \Delta x \quad (9)$$

so that

$$x = a + \Delta x \equiv x_0 + \Delta x. \quad (10)$$

Substitute this result into (5) to give

$$f(x_0 + \Delta x) = f(x_0) + \Delta x f'(x_0) + \frac{1}{2!}(\Delta x)^2 f''(x_0) + \cdots \quad (11)$$

A Taylor series of a FUNCTION in two variables  $f(x, y)$  is given by

$$\begin{aligned} f(x + \Delta x, y + \Delta y) &= f(x, y) + [f_x(x, y)\Delta x + f_y(x, y)\Delta y] \\ &\quad + \frac{1}{2!}[(\Delta x)^2 f_{xx}(x, y) + 2\Delta x\Delta y f_{xy}(x, y) + (\Delta y)^2 f_{yy}(x, y)] \\ &\quad + \frac{1}{3!}[(\Delta x)^3 f_{xxx}(x, y) + 3(\Delta x)^2\Delta y f_{xxy}(x, y) \\ &\quad + 3\Delta x(\Delta y)^2 f_{xyy}(x, y) + (\Delta y)^3 f_{yyy}(x, y)] + \cdots \end{aligned} \quad (12)$$

This can be further generalized for a FUNCTION in  $n$  variables,

$$\begin{aligned} &f(x_1, \dots, x_n) \\ &= \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left[ \sum_{k=1}^n (x'_k - a_k) \frac{\partial}{\partial x'_k} \right]^j f(x'_1, \dots, x'_n) \right\}_{x'_1=a_1, \dots, x'_n=a_n}. \end{aligned} \quad (13)$$

Rewriting,

$$f(x_1 + a_1, \dots, x_n + a_n) = \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left( \sum_{k=1}^n a_k \frac{\partial}{\partial x'_k} \right)^j f(x'_1, \dots, x'_n) \right\}_{x'_1=x_1, \dots, x'_n=x_n} \quad (14)$$

Taking  $n = 2$  in (13) gives

$$\begin{aligned} f(x_1, x_2) &= \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left[ (x'_1 - a_1) \frac{\partial}{\partial x'_1} + (x'_2 - a_2) \frac{\partial}{\partial x'_2} \right]^j f(x'_1, x'_2) \right\}_{x'_1=x_1, x'_2=x_2} \\ &= f(a_1, a_2) + \left[ (x_1 - a_1) \frac{\partial f}{\partial x_1} + (x_2 - a_2) \frac{\partial f}{\partial x_2} \right] \\ &\quad + \frac{1}{2!} \left[ (x_1 - a_1)^2 \frac{\partial^2 f}{\partial x_1^2} + 2(x_1 - a_1)(x_2 - a_2) \frac{\partial^2 f}{\partial x_1 \partial x_2} \right. \\ &\quad \left. + (x_2 - a_2)^2 \frac{\partial^2 f}{\partial x_2^2} \right] + \dots \quad (15) \end{aligned}$$

Taking  $n = 3$  in (14) gives

$$\begin{aligned} f(x_1 + a_1, x_2 + a_2, x_3 + a_3) &= \sum_{j=0}^{\infty} \left\{ \frac{1}{j!} \left( a_1 \frac{\partial}{\partial x'_1} + a_2 \frac{\partial}{\partial x'_2} + a_3 \frac{\partial}{\partial x'_3} \right)^j \right. \\ &\quad \left. \times f(x'_1, x'_2, x'_3) \right\}_{x'_1=x_1, x'_2=x_2, x'_3=x_3} \quad (16) \end{aligned}$$

or, in VECTOR form

$$f(\mathbf{r} + \mathbf{a}) = \sum_{j=0}^{\infty} \left[ \frac{1}{j!} (\mathbf{a} \cdot \nabla_{\mathbf{r}'})^j f(\mathbf{r}') \right]_{\mathbf{r}'=\mathbf{r}} \quad (17)$$

The zeroth- and first-order terms are

$$f(\mathbf{r}) \quad (18)$$

and

$$(\mathbf{a} \cdot \nabla_{\mathbf{r}'}) f(\mathbf{r}')|_{\mathbf{r}'=\mathbf{r}}, \quad (19)$$

respectively. The second-order term is

$$\begin{aligned} \frac{1}{2} (\mathbf{a} \cdot \nabla_{\mathbf{r}'}) (\mathbf{a} \cdot \nabla_{\mathbf{r}'}) f(\mathbf{r}')|_{\mathbf{r}'=\mathbf{r}} &= \frac{1}{2} \mathbf{a} \cdot \nabla_{\mathbf{r}'} [\mathbf{a} \cdot (\nabla f(\mathbf{r}'))]_{\mathbf{r}'=\mathbf{r}} \\ &= \frac{1}{2} \mathbf{a} \cdot [\mathbf{a} \cdot \nabla_{\mathbf{r}'} (\nabla_{\mathbf{r}'} f(\mathbf{r}'))]_{\mathbf{r}'=\mathbf{r}}, \quad (20) \end{aligned}$$

so the first few terms of the expansion are

$$\begin{aligned} f(\mathbf{r} + \mathbf{a}) &= f(\mathbf{r}) + (\mathbf{a} \cdot \nabla_{\mathbf{r}'}) f(\mathbf{r}')|_{\mathbf{r}'=\mathbf{r}} \\ &\quad + \frac{1}{2} \mathbf{a} \cdot [\mathbf{a} \cdot \nabla_{\mathbf{r}'} (\nabla_{\mathbf{r}'} f(\mathbf{r}'))]_{\mathbf{r}'=\mathbf{r}}. \quad (21) \end{aligned}$$

Taylor series can also be defined for functions of a COMPLEX variable. By the CAUCHY INTEGRAL FORMULA,

$$\begin{aligned} f(z) &= \frac{1}{2\pi i} \int_C \frac{f(z') dz'}{z' - z} = \frac{1}{2\pi i} \int_C \frac{f(z') dz'}{(z' - z_0) - (z - z_0)} \\ &= \frac{1}{2\pi i} \int_C \frac{f(z') dz'}{(z' - z_0) \left(1 - \frac{z - z_0}{z' - z_0}\right)}. \quad (22) \end{aligned}$$

In the interior of  $C$ ,

$$\frac{|z - z_0|}{|z' - z_0|} < 1 \quad (23)$$

so, using

$$\frac{1}{1-t} = \sum_{n=0}^{\infty} t^n, \quad (24)$$

it follows that

$$\begin{aligned} f(z) &= \frac{1}{2\pi i} \int_C \sum_{n=0}^{\infty} \frac{(z - z_0)^n f(z') dz'}{(z' - z_0)^{n+1}} \\ &= \frac{1}{2\pi i} \sum_{n=0}^{\infty} (z - z_0)^n \int_C \frac{f(z') dz'}{(z' - z_0)^{n+1}}. \quad (25) \end{aligned}$$

Using the the CAUCHY INTEGRAL FORMULA for derivatives,

$$f(z) = \sum_{n=0}^{\infty} (z - z_0)^n \frac{f^{(n)}(z_0)}{n!}. \quad (26)$$

**Telescoping Sum**

A sum in which subsequent terms cancel each other, leaving only initial and final terms. For example,

$$\begin{aligned}S &= \sum_{i=1}^{n-1} \left( \frac{1}{a_i} - \frac{1}{a_{i+1}} \right) \\ &= \left( \frac{1}{a_1} - \frac{1}{a_2} \right) + \left( \frac{1}{a_2} - \frac{1}{a_3} \right) + \dots \\ &\quad + \left( \frac{1}{a_{n-2}} - \frac{1}{a_{n-1}} \right) + \left( \frac{1}{a_{n-1}} - \frac{1}{a_n} \right) \\ &= \frac{1}{a_1} - \frac{1}{a_n}\end{aligned}$$

is a telescoping sum.

see also ZEILBERGER'S ALGORITHM

**Temperature**

The "temperature" of a curve  $\Gamma$  is defined as

$$T \equiv \frac{1}{\ln\left(\frac{2l}{2l-h}\right)},$$

where  $l$  is the length of  $\Gamma$  and  $h$  is the length of the PERIMETER of the CONVEX HULL. The temperature of a curve is 0 only if the curve is a straight line, and increases as the curve becomes more "wiggly."

## Tensor

An  $n$ th-RANK tensor of order  $m$  is a mathematical object in  $m$ -dimensional space which has  $n$  indices and  $m^n$  components and obeys certain transformation rules. Each index of a tensor ranges over the number of dimensions of SPACE. If the components of any tensor of any RANK vanish in one particular coordinate system, they vanish in all coordinate systems.

Zeroth-RANK tensors are called SCALARS, and first-RANK tensors are called VECTORS. In tensor notation, a vector  $\mathbf{v}$  would be written  $v_i$ , where  $i = 1, \dots, m$ . Tensor notation can provide a very concise way of writing vector and more general identities. For example, in tensor notation, the DOT PRODUCT  $\mathbf{u} \cdot \mathbf{v}$  is simply written

$$\mathbf{u} \cdot \mathbf{v} = u_i v_i, \quad (1)$$

where repeated indices are summed over (EINSTEIN SUMMATION) so that  $u_i v_i$  stands for  $u_1 v_1 + \dots + u_m v_m$ . Similarly, the CROSS PRODUCT can be concisely written as

$$\mathbf{u} \times \mathbf{v} = \epsilon_{ijk} u^j v^k, \quad (2)$$

where  $\epsilon_{ijk}$  is the LEVI-CIVITA TENSOR.

Second-RANK tensors resemble square MATRICES. CONTRAVARIANT second-RANK tensors are objects which transform as

$$A'^{ij} = \frac{\partial x'_i}{\partial x_k} \frac{\partial x'_j}{\partial x_l} A^{kl}. \quad (3)$$

COVARIANT second-RANK tensors are objects which transform as

$$C'_{ij} = \frac{\partial x_k}{\partial x'_i} \frac{\partial x_l}{\partial x'_j} C_{kl}. \quad (4)$$

MIXED second-RANK tensors are objects which transform as

$$B'^j_i = \frac{\partial x'_j}{\partial x_k} \frac{\partial x_l}{\partial x'_i} B^k_l. \quad (5)$$

If two tensors  $A$  and  $B$  have the same RANK and the same COVARIANT and CONTRAVARIANT indices, then

$$A^{ij} + B^{ij} = C^{ij} \quad (6)$$

$$A_{ij} + B_{ij} = C_{ij} \quad (7)$$

$$A^i_j + B^i_j = C^i_j. \quad (8)$$

A transformation of the variables of a tensor changes the tensor into another whose components are linear HOMOGENEOUS FUNCTIONS of the components of the original tensor.

## Tensor Spherical Harmonic

see DOUBLE CONTRACTION RELATION

**Tensor Transpose**

see TRANSPOSE

**Tent Map**

A piecewise linear, 1-D MAP on the interval  $[0, 1]$  exhibiting CHAOTIC dynamics and given by

$$x_{n+1} = \mu(1 - 2|x_n - \frac{1}{2}|).$$

The case  $\mu = 1$  is equivalent to the LOGISTIC EQUATION WITH  $r = 4$ , so the NATURAL INVARIANT in this case is

$$\rho(x) = \frac{1}{\pi \sqrt{x(1-x)}}.$$

see also  $2x \bmod 1$  MAP, LOGISTIC EQUATION, LOGISTIC EQUATION WITH  $r = 4$

**Terminal**

see SINK (DIRECTED GRAPH)

**Ternary**

The BASE 3 method of counting in which only the digits 0, 1, and 2 are used. These digits have the following multiplication table.

$\times$	0	1	2
0	0	0	0
1	0	1	2
2	0	2	11

Erdős and Graham (1980) conjectured that no POWER of 2,  $2^n$ , is a SUM of distinct powers of 3 for  $n > 8$ . This is equivalent to the requirement that the ternary expansion of  $2^n$  always contains a 2. This has been verified by Vardi (1991) up to  $n = 2 \cdot 3^{20}$ . N. J. A. Sloane has conjectured that any POWER of 2 has a 0 in its ternary expansion (Vardi 1991, p. 28).

**Tessellation**

A regular TILING of POLYGONS (in 2-D), POLYHEDRA (3-D), or POLYTOPES ( $n$ -D) is called a tessellation. Tessellations can be specified using a SCHLÄFLI SYMBOL.

Consider a 2-D tessellation with  $q$  regular  $p$ -gons at each VERTEX. In the PLANE,

$$\left(1 - \frac{2}{p}\right) \pi = \frac{2\pi}{q} \quad (1)$$

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{2}, \quad (2)$$

so

$$(p-2)(q-2) = 4 \quad (3)$$

(Ball and Coxeter 1987), and the only factorizations are

$$4 = 4 \cdot 1 = (6-2)(3-2) \Rightarrow \{6, 3\} \quad (4)$$

$$= 2 \cdot 2 = (4-2)(4-2) \Rightarrow \{4, 4\} \quad (5)$$

$$= 1 \cdot 4 = (3-2)(6-2) \Rightarrow \{3, 6\}. \quad (6)$$

Therefore, there are only three regular tessellations (composed of the HEXAGON, SQUARE, and TRIANGLE), illustrated as follows.

There do not exist any regular STAR POLYGON tessellations in the PLANE. Regular tessellations of the SPHERE by SPHERICAL TRIANGLES are called TRIANGULAR SYMMETRY GROUPS.

Regular tilings of the plane by *two or more* convex regular POLYGONS such that the same POLYGONS in the same order surround each VERTEX are called semiregular tilings. In the plane, there are eight such tessellations, illustrated below.

In 3-D, a POLYHEDRON which is capable of tessellating space is called a 'SPACE-FILLING POLYHEDRON. Examples include the CUBE, RHOMBIC DODECAHEDRON, and TRUNCATED OCTAHEDRON. There is also a 16-sided space-filler and a convex POLYHEDRON known as the SCHMITT-CONWAY BIPRISM which fills space only aperiodically.

A tessellation of  $n$ -D polytopes is called a HONEYCOMB. *see also* ARCHIMEDEAN SOLID, CELL, HONEYCOMB, SCHLÄFLI SYMBOL, SEMIREGULAR POLYHEDRON, SPACE-FILLING POLYHEDRON, TILING, TRIANGULAR SYMMETRY GROUP

**Tetrahedral Number**

A FIGURATE NUMBER  $Te_n$  of the form

$$Te_n = \sum_{i=1}^n T_n = \frac{1}{6}n(n+1)(n+2) = \binom{n+2}{3}, \quad (1)$$

where  $T_n$  is the  $n$ th TRIANGULAR NUMBER and  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT. These numbers correspond to placing discrete points in the configuration of a TETRAHEDRON (triangular base pyramid). Tetrahedral numbers are PYRAMIDAL NUMBERS with  $r = 3$ , and are the sum of consecutive TRIANGULAR NUMBERS. The first few are 1, 4, 10, 20, 35, 56, 84, 120, ... (Sloane's

A000292). The GENERATING FUNCTION of the tetrahedral numbers is

$$\frac{x}{(x-1)^4} = x + 4x^2 + 10x^3 + 20x^4 + \dots \quad (2)$$

Tetrahedral numbers are EVEN, except for every fourth tetrahedral number, which is ODD (Conway and Guy 1996).

The only numbers which are simultaneously SQUARE and TETRAHEDRAL are  $Te_1 = 1$ ,  $Te_2 = 4$ , and  $Te_{48} = 19600$  (giving  $S_1 = 1$ ,  $S_2 = 4$ , and  $S_{140} = 19600$ ), as proved by Meyl (1878; cited in Dickson 1952, p. 25). Numbers which are simultaneously TRIANGULAR and tetrahedral satisfy the BINOMIAL COEFFICIENT equation

$$\binom{n}{2} = \binom{m}{3}, \quad (3)$$

the only solutions of which are  $(m, n) = (10, 16)$ ,  $(22, 56)$ , and  $(36, 120)$  (Guy 1994, p. 147). Beukers (1988) has studied the problem of finding numbers which are simultaneously tetrahedral and PYRAMIDAL via INTEGER points on an ELLIPTIC CURVE, and finds that the only solution is the trivial  $Te_1 = P_1 = 1$ .

**Tetrahedron**

The regular tetrahedron, often simply called “the” tetrahedron, is the PLATONIC SOLID  $P_1$  with four VERTICES, six EDGES, and four equivalent EQUILATERAL TRIANGULAR faces  $(4\{3\})$ . It is also UNIFORM POLYHEDRON  $U_1$ . It is described by the SCHLÄFLI SYMBOL  $\{3, 3\}$  and the WYTHOFF SYMBOL is  $3|23$ . It is the prototype of the TETRAHEDRAL GROUP  $T_d$ ,

The tetrahedron is its own DUAL POLYHEDRON. It is the only simple POLYHEDRON with no DIAGONALS, and cannot be STELLATED. The VERTICES of a tetrahedron are given by  $(0, 0, \sqrt{3})$ ,  $(0, \frac{2}{3}\sqrt{6}, -\frac{1}{3}\sqrt{3})$ ,  $(-\sqrt{2}, -\frac{1}{3}\sqrt{6}, -\frac{1}{3}\sqrt{3})$ , and  $(\sqrt{2}, -\frac{1}{3}\sqrt{6}, -\frac{1}{3}\sqrt{3})$ , or by  $(0, 0, 0)$ ,  $(0, 1, 1)$ ,  $(1, 0, 1)$ ,  $(1, 1, 0)$ . In the latter case, the face planes are

$$x + y + z = 2 \quad (1)$$

$$x - y - z = 0 \quad (2)$$

$$-x + y - z = 0 \quad (3)$$

$$x + y - z = 0. \quad (4)$$

Let a tetrahedron be length  $a$  on a side. The VERTICES are located at  $(x, 0, 0)$ ,  $(-d, \pm a/2, 0)$ , and  $(0, 0, h)$ . From the figure,

Perspective View

Bottom View

Side View

$$x = \frac{\frac{a}{2}}{\cos(\frac{\pi}{6})} = \frac{1}{2} \frac{2}{\sqrt{3}} a = \frac{1}{3} \sqrt{3} a. \quad (5)$$

$d$  is then

$$\begin{aligned} d &= \sqrt{x^2 - (\frac{1}{2}a)^2} = a\sqrt{\frac{1}{3} - \frac{1}{4}} = a\sqrt{\frac{4-3}{12}} = \frac{a}{\sqrt{12}} \\ &= \frac{1}{6}\sqrt{3}a. \end{aligned} \quad (6)$$

This gives the AREA of the base as

$$\begin{aligned} A &= \frac{1}{2}a(R + x) = \frac{1}{2}a\left(\frac{\sqrt{3}}{6}a + \frac{1}{\sqrt{3}}a\right) \\ &= \frac{1}{2}a^2\left(\frac{\sqrt{3}}{6} + \frac{2\sqrt{3}}{6}\right) \\ &= \frac{1}{2}a^2\frac{3\sqrt{3}}{6} = \frac{1}{4}\sqrt{3}a^2. \end{aligned} \quad (7)$$

The height is

$$h = \sqrt{a^2 - x^2} = a\sqrt{1 - \frac{1}{3}} = \frac{1}{3}\sqrt{6}a. \quad (8)$$

The CIRCUMRADIUS  $R$  is found from

$$x^2 + (h - R)^2 = R^2 \quad (9)$$

$$x^2 + h^2 - 2hR + R^2 = R^2. \quad (10)$$

Solving gives

$$R = \frac{x^2 + h^2}{2h} = \frac{\frac{1}{3} + \frac{2}{3}}{2\sqrt{\frac{2}{3}}} = \frac{1}{2}\sqrt{\frac{3}{2}} = \frac{1}{4}\sqrt{6}a \approx 0.61237a. \quad (11)$$

The INRADIUS  $r$  is

$$r \equiv h - R = \sqrt{\frac{2}{3}}a - \frac{\sqrt{3}}{6}a = \frac{1}{12}\sqrt{6}a \approx 0.20412a, \quad (12)$$

which is also

$$r = \frac{1}{4}h = \frac{1}{3}R. \quad (13)$$

The MIDRADIUS is

$$\begin{aligned} \rho &= \sqrt{r^2 + d^2} = a\sqrt{\frac{6}{144} + \frac{3}{36}} = \sqrt{\frac{1}{8}}a = \frac{1}{4}\sqrt{2}a \\ &\approx 0.35355a. \end{aligned} \quad (14)$$

Plugging in for the VERTICES gives

$$(a\sqrt{3}, 0, 0), (-\frac{1}{6}\sqrt{3}a, \pm\frac{1}{2}a, 0), \text{ and } (0, 0, \frac{1}{3}\sqrt{6}a). \quad (15)$$

Since a tetrahedron is a PYRAMID with a triangular base,  $V = \frac{1}{3}A_b h$ , and

$$V = \frac{1}{3}\left(\frac{1}{4}\sqrt{3}a^2\right)\left(\sqrt{\frac{2}{3}}a\right) = \frac{1}{12}\sqrt{2}a^3. \quad (16)$$

The DIHEDRAL ANGLE is

$$\theta = \tan^{-1}(2\sqrt{2}) = 2\sin^{-1}(\frac{1}{3}\sqrt{6}) = \cos^{-1}(\frac{1}{3}). \quad (17)$$

By slicing a tetrahedron as shown above, a SQUARE can be obtained. This cut divides the tetrahedron into two congruent solids rotated by  $90^\circ$ .

Now consider a general (not necessarily regular) tetrahedron, defined as a convex POLYHEDRON consisting of four (not necessarily identical) TRIANGULAR faces. Let the tetrahedron be specified by its VERTICES at  $(x_i, y_i)$  where  $i = 1, \dots, 4$ . Then the VOLUME is given by

$$V = \frac{1}{3!} \begin{vmatrix} x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \\ x_4 & y_4 & z_4 & 1 \end{vmatrix}. \quad (18)$$

Specifying the tetrahedron by the three EDGE vectors  $\mathbf{a}$ ,  $\mathbf{b}$ , and  $\mathbf{c}$  from a given VERTEX, the VOLUME is

$$V = \frac{1}{3!} |\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})|. \quad (19)$$

If the faces are congruent and the sides have lengths  $a$ ,  $b$ , and  $c$ , then

$$V = \sqrt{\frac{(a^2 + b^2 - c^2)(a^2 + c^2 - b^2)(b^2 + c^2 - a^2)}{72}} \quad (20)$$

(Klee and Wagon 1991, p. 205). Let  $a$ ,  $b$ ,  $c$ , and  $d$  be the areas of the four faces, and define

$$B \equiv \angle cd \quad (21)$$

$$C \equiv \angle bd \quad (22)$$

$$D \equiv \angle bc, \quad (23)$$

where  $\angle jk$  means here the ANGLE between the PLANES formed by the FACES  $j$  and  $k$ , with VERTEX along their intersecting EDGE. Then

$$a^2 = b^2 + c^2 + d^2 - 2cd \cos B - 2bd \cos C - 2bc \cos D. \quad (24)$$

The analog of GAUSS'S CIRCLE PROBLEM can be asked for tetrahedra: how many LATTICE POINTS lie within a tetrahedron centered at the ORIGIN with a given INRADIUS (Lehmer 1940, Granville 1991, Xu and Yau 1992, Guy 1994).

## Tetrahedron Inscribing

Pick four points at random on the surface of a unit SPHERE. Find the distribution of possible volumes of (nonregular) TETRAHEDRA. Without loss of generality, the first point can be chosen as (1, 0, 0). Designate the other points **a**, **b**, and **c**. Then the distances from the first VERTEX are

$$\mathbf{a} = \begin{bmatrix} \cos \theta_1 - 1 \\ \sin \theta_1 \\ 0 \end{bmatrix} \quad (1)$$

$$\mathbf{b} = \begin{bmatrix} \cos \theta_2 \sin \phi_2 - 1 \\ \sin \theta_2 \sin \phi_2 \\ \cos \phi_2 \end{bmatrix} \quad (2)$$

$$\mathbf{c} = \begin{bmatrix} \cos \theta_3 \sin \phi_3 - 1 \\ \sin \theta_3 \sin \phi_3 \\ \cos \phi_3 \end{bmatrix}. \quad (3)$$

The average volume is then

$$\bar{V} = \frac{1}{C} \int_0^{2\pi} \int_0^{2\pi} \int_0^{2\pi} \int_{-\pi/2}^{\pi/2} \int_{-\pi/2}^{\pi/2} \frac{1}{3!} |\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})| d\phi_3 d\phi_2 d\theta_3 d\theta_2 d\theta_1, \quad (4)$$

where

$$C = \int_0^{2\pi} \int_0^{2\pi} \int_0^{2\pi} \int_{-\pi/2}^{\pi/2} d\phi_3 d\phi_2 d\theta_3 d\theta_2 d\theta_1 = 8\pi^5 \quad (5)$$

and

$$\begin{aligned} \mathbf{a} \cdot (\mathbf{b} \times \mathbf{c}) = & -\cos \phi_2 \sin \theta_1 + \cos \phi_3 \sin \theta_1 \\ & -\cos \phi_3 \cos \theta_2 \sin \phi_2 \sin \theta_1 + \cos \phi_2 \cos \theta_3 \sin \phi_3 \sin \theta_1 \\ & -\cos \phi_3 \sin \phi_2 \sin \theta_2 + \cos \phi_3 \cos \theta_1 \sin \phi_2 \sin \theta_2 \\ & +\cos \phi_2 \sin \phi_3 \sin \theta_3 - \cos \phi_2 \cos \theta_1 \sin \phi_3 \sin \theta_3. \end{aligned} \quad (6)$$

The integrals are difficult to compute analytically, but  $10^7$  computer TRIALS give

$$\langle V \rangle \approx 0.1080 \quad (7)$$

$$\langle V^2 \rangle \approx 0.02128 \quad (8)$$

$$\sigma_V^2 = \langle V^2 \rangle - \langle V \rangle^2 \approx 0.009937. \quad (9)$$

**Tetrakis Hexahedron**

The DUAL POLYHEDRON of the TRUNCATED OCTAHEDRON.

**Tetranacci Number**

The tetranacci numbers are a generalization of the FIBONACCI NUMBERS defined by  $T_0 = 0$ ,  $T_1 = 1$ ,  $T_2 = 1$ ,  $T_3 = 2$ , and the RECURRENCE RELATION

$$T_n = T_{n-1} + T_{n-2} + T_{n-3} + T_{n-4}$$

for  $n \geq 4$ . They represent the  $n = 4$  case of the FIBONACCI  $n$ -STEP NUMBERS. The first few terms are 1, 1, 2, 4, 8, 15, 29, 56, 108, 208, ... (Sloane's A000078). The ratio of adjacent terms tends to 1.92756, which is the REAL ROOT of  $x^5 - 2x^4 + 1 = 0$ .

see also FIBONACCI  $n$ -STEP NUMBER, FIBONACCI NUMBER, TRIBONACCI NUMBER

**References**

Sloane, N. J. A. Sequence A000078/M1108 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Tetrix**

The 3-D analog of the SIERPIŃSKI SIEVE illustrated above, also called the SIERPIŃSKI SPONGE or SIERPIŃSKI TETRAHEDRON. Let  $N_n$  be the number of tetrahedra,  $L_n$  the length of a side, and  $A_n$  the fractional VOLUME of tetrahedra after the  $n$ th iteration. Then

$$N_n = 4^n \quad (1)$$

$$L_n = \left(\frac{1}{2}\right)^n = 2^{-n} \quad (2)$$

$$A_n = L_n^3 N_n = \left(\frac{1}{2}\right)^n. \quad (3)$$

The CAPACITY DIMENSION is therefore

$$\begin{aligned} d_{\text{cap}} &= - \lim_{n \rightarrow \infty} \frac{\ln N_n}{\ln L_n} = - \lim_{n \rightarrow \infty} \frac{\ln(4^n)}{\ln(2^{-n})} \\ &= \frac{\ln 4}{\ln 2} = \frac{2 \ln 2}{\ln 2} = 2, \end{aligned} \quad (4)$$

so the tetrix has an INTEGRAL CAPACITY DIMENSION (albeit one less than the DIMENSION of the 3-D TETRAHEDRA from which it is built), despite the fact that it is a FRACTAL.

The following illustration demonstrates how this counterintuitive fact can be true by showing three stages of the rotation of a tetrix, viewed along one of its edges. In the last frame, the tetrix "looks" like the 2-D PLANE.

**Thales' Theorem**

An ANGLE inscribed in a SEMICIRCLE is a RIGHT ANGLE.

see also RIGHT ANGLE, SEMICIRCLE

**Theorem**

A statement which can be demonstrated to be true by accepted mathematical operations and arguments. In general, a theorem is an embodiment of some general principle that makes it part of a larger theory.

According to the Nobel Prize-winning physicist Richard Feynman (1985), any theorem, no matter how difficult to prove in the first place, is viewed as "TRIVIAL"

by mathematicians once it has been proven. Therefore, there are exactly two types of mathematical objects: TRIVIAL ones, and those which have not yet been proven.

### Theorema Egregium

see GAUSS'S THEOREMA EGREGIUM

### Theta Function

The theta functions are the elliptic analogs of the EXPONENTIAL FUNCTION, and may be used to express the JACOBI ELLIPTIC FUNCTIONS. Let  $t$  be a constant COMPLEX NUMBER with  $\Im[t] > 0$ . Define the NOME

$$q \equiv e^{i\pi t} = e^{\pi K'(k)/K(k)}, \quad (1)$$

where

$$t \equiv -i \frac{K'(k)}{K(k)}, \quad (2)$$

and  $K(k)$  is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND,  $k$  is the MODULUS, and  $k'$  is the complementary MODULUS. Then the theta functions are, in the NOTATION of Whittaker and Watson,

$$\begin{aligned} \vartheta_1(z, q) &\equiv 2 \sum_{n=0}^{\infty} (-1)^n q^{(n+1/2)^2} \sin[(2n+1)z] \\ &= z q^{1/4} \sum_{n=0}^{\infty} (-1)^n q^{n(n+1)} \sin[(2n+1)z] \end{aligned} \quad (3)$$

$$\begin{aligned} \vartheta_2(z, q) &\equiv 2 \sum_{n=0}^{\infty} q^{(n+1/2)^2} \cos[(2n+1)z] \\ &= 2q^{1/4} \sum_{n=0}^{\infty} q^{n(n+1)} \cos[(2n+1)z] \end{aligned} \quad (4)$$

$$\vartheta_3(z, q) \equiv 1 + 2 \sum_{n=1}^{\infty} q^{n^2} \cos(2nz) \quad (5)$$

$$\begin{aligned} \vartheta_4(z, q) &\equiv \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} e^{2niz} \\ &= 1 + 2 \sum_{n=1}^{\infty} (-1)^n q^{n^2} \cos(2nz). \end{aligned} \quad (6)$$

Written in terms of  $t$ ,

$$\vartheta_2(t, q) = \sum_{n=-\infty}^{\infty} q^{(n+1/2)^2} e^{\Im[t]} \quad (7)$$

$$\vartheta_3(t, q) = \sum_{n=-\infty}^{\infty} q^{n^2} e^{\Im[t]}. \quad (8)$$

These functions are sometimes denoted  $\Theta_i$  or  $\theta_i$ , and a number of indexing conventions have been used. For a summary of these notations, see Whittaker and Watson (1990). The theta functions are quasidoubly periodic, as illustrated in the following table.

$\vartheta_i$	$\vartheta_i(z + \pi)/\vartheta_i(z)$	$\vartheta_i(z + t\pi)/\vartheta_i(z)$
$\vartheta_1$	-1	$-N$
$\vartheta_2$	-1	$N$
$\vartheta_3$	1	$N$
$\vartheta_4$	1	$-N$

Here,

$$N \equiv q^{-1} e^{-2iz}. \quad (9)$$

The quasiperiodicity can be established as follows for the specific case of  $\vartheta_4$ ,

$$\begin{aligned} \vartheta_4(z + \pi, q) &= \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} e^{2niz} e^{2ni\pi} \\ &= \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} e^{2niz} = \vartheta_4(z, q) \quad (10) \\ \vartheta_4(z + \pi t, q) &= \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} e^{2n\pi i t} e^{2niz} \\ &= \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} q^{2n} e^{2niz} \\ &= -q^{-1} e^{-2iz} \sum_{n=-\infty}^{\infty} (-1)^{n+1} q^{(n+1)^2} q^{2(n+1)iz} \\ &= -q^{-1} e^{-2iz} \sum_{n=-\infty}^{\infty} (-1)^n q^{n^2} q^{2niz} \\ &= -q^{-1} e^{-2iz} \vartheta_4(z, q). \end{aligned} \quad (11)$$

The theta functions can be written in terms of each other:

$$\vartheta_1(z, q) = -ie^{iz+\pi it/4} \vartheta_4(z + \frac{1}{4}\pi t, q) \quad (12)$$

$$\vartheta_2(z, q) = \vartheta_1(z + \frac{1}{2}\pi, q) \quad (13)$$

$$\vartheta_3(z, q) = \vartheta_4(z + \frac{1}{2}\pi, q). \quad (14)$$

Any theta function of given arguments can be expressed in terms of any other two theta functions with the same arguments.

Define

$$\vartheta_i \equiv \vartheta_i(z=0), \quad (15)$$

which are plotted above. Then we have the identities

$$\vartheta_1^2(z)\vartheta_4^2 = \vartheta_3^2(z)\vartheta_2^2 - \vartheta_2^2(z)\vartheta_3^2 \quad (16)$$

$$\vartheta_2^2(z)\vartheta_4^2 = \vartheta_4^2(z)\vartheta_2^2 - \vartheta_1^2(z)\vartheta_3^2 \quad (17)$$

$$\vartheta_3^2(z)\vartheta_4^2 = \vartheta_4^2(z)\vartheta_3^2 - \vartheta_1^2(z)\vartheta_2^2 \quad (18)$$

$$\vartheta_4^2(z)\vartheta_4^2 = \vartheta_3^2(z)\vartheta_3^2 - \vartheta_2^2(z)\vartheta_2^2. \quad (19)$$

Taking  $z = 0$  in the last gives the special case

$$\vartheta_4^4 = \vartheta_3^4 - \vartheta_2^4. \quad (20)$$

In addition,

$$\vartheta_3(x) = \sum_{n=-\infty}^{\infty} x^{n^2} = 1 + 2x + 2x^4 + 2x^9 + \dots \quad (21)$$

$$\vartheta_3^2(x) = 1 + 4 \left( \frac{x}{1-x} - \frac{x^3}{1-x^3} + \frac{x^5}{1-x^5} - \frac{x^7}{1-x^7} + \dots \right) \quad (22)$$

$$\vartheta_3^4(x) = 1 + 8 \left( \frac{x}{1-x} + \frac{2x^2}{1+x^2} + \frac{3x^3}{1-x^3} + \frac{4x^4}{1+x^4} + \dots \right). \quad (23)$$

The theta functions obey addition rules such as

$$\vartheta_3(z+y)\vartheta_3(z-y)\vartheta_3^2 = \vartheta_3^2(y)\vartheta_3^2(z) + \vartheta_1^2(y)\vartheta_1^2(z). \quad (24)$$

Letting  $y = z$  gives a duplication FORMULA

$$\vartheta_3(2z)\vartheta_3^3 = \vartheta_3^4(z) + \vartheta_1^4(z). \quad (25)$$

For more addition FORMULAS, see Whittaker and Watson (1990, pp. 487–488). Ratios of theta function derivatives to the functions themselves have the simple forms

$$\frac{\vartheta_1'(z)}{\vartheta_1(z)} = \cot z + 4 \sum_{n=1}^{\infty} \frac{q^{2n}}{1-q^{2n}} \sin(2nz) \quad (26)$$

$$\frac{\vartheta_2'(z)}{\vartheta_2(z)} = -\tan z + 4 \sum_{n=1}^{\infty} (-1)^n \frac{q^{2n}}{1-q^{2n}} \sin(2nz) \quad (27)$$

$$\frac{\vartheta_3'(z)}{\vartheta_3(z)} = 4 \sum_{n=1}^{\infty} (-1)^n \frac{q^n}{1-q^{2n}} \sin(2nz) \quad (28)$$

$$\begin{aligned} \frac{\vartheta_4'(z)}{\vartheta_4(z)} &= \sum_{n=1}^{\infty} \frac{q^{2n-1} \sin(2z)}{1-2q^{2n-1} \cos(2z) + q^{4n-2}} \\ &= \sum_{n=1}^{\infty} \frac{4q^n \sin(2nz)}{1-q^{2n}}. \end{aligned} \quad (29)$$

The theta functions can be expressed as products instead of sums by

$$\vartheta_1(z) = 2Gq^{1/4} \sin z \prod_{n=1}^{\infty} [1 - 2q^{2n} \cos(2z) + q^{4n}] \quad (30)$$

$$\vartheta_2(z) = 2Gq^{1/4} \cos z \prod_{n=1}^{\infty} [1 + 2q^{2n} \cos(2z) + q^{4n}] \quad (31)$$

$$\vartheta_3(z) = G \prod_{n=1}^{\infty} [1 + 2q^{2n-1} \cos(2z) + q^{4n-2}] \quad (32)$$

$$\vartheta_4(z) = G \prod_{n=1}^{\infty} [1 - 2q^{2n-1} \cos(2z) + q^{4n-2}], \quad (33)$$

where

$$G \equiv \prod_{n=1}^{\infty} (1 - q^{2n}) \quad (34)$$

(Whittaker and Watson 1990, pp. 469–470).

The theta functions satisfy the PARTIAL DIFFERENTIAL EQUATION

$$\frac{1}{4} \pi i \frac{\partial^2 y}{\partial z^2} + \frac{\partial y}{\partial t} = 0, \quad (35)$$

where  $y \equiv \vartheta_j(z|t)$ . Ratios of the theta functions with  $\vartheta_4$  in the DENOMINATOR also satisfy differential equations

$$\frac{d}{dz} \left[ \frac{\vartheta_1(z)}{\vartheta_4(z)} \right] = \vartheta_4^2 \frac{\vartheta_2(z)\vartheta_3(z)}{\vartheta_4^2(z)} \quad (36)$$

$$\frac{d}{dz} \left[ \frac{\vartheta_2(z)}{\vartheta_4(z)} \right] = -\vartheta_3^2 \frac{\vartheta_1(z)\vartheta_3(z)}{\vartheta_4^2(z)} \quad (37)$$

$$\frac{d}{dz} \left[ \frac{\vartheta_3(z)}{\vartheta_4(z)} \right] = -\vartheta_2^2 \frac{\vartheta_1(z)\vartheta_2(z)}{\vartheta_4^2(z)}. \quad (38)$$

Some additional remarkable identities are

$$\vartheta_1' = \vartheta_2\vartheta_3\vartheta_4 \quad (39)$$

$$\vartheta_3(z, t) = -(it)^{1/2} e^{z^2/\pi it} \vartheta_3 \left( \frac{2}{t}, -\frac{1}{t} \right), \quad (40)$$

which were discovered by Poisson in 1827 and are equivalent to

$$\sum_{n=-\infty}^{\infty} e^{-t(x+n)^2} = \sqrt{\frac{\pi}{t}} \sum_{k=-\infty}^{\infty} 2^{2\pi i k x - (\pi^2 k^2/t)}. \quad (41)$$

Another amazing identity is

$$\begin{aligned} 2\vartheta_1[\tfrac{1}{2}(-b+c+d+e)]\vartheta_2[\tfrac{1}{2}(b-c+d+e)]\vartheta_3[\tfrac{1}{2}(b+c-d+e)] \\ \times \vartheta_4[\tfrac{1}{2}(b+c+d-e)] = \vartheta_3(b)\vartheta_4(c)\vartheta_1(d)\vartheta_2(e) \\ + \vartheta_2(b)\vartheta_1(c)\vartheta_4(d)\vartheta_3(e) - \vartheta_1(b)\vartheta_2(c)\vartheta_3(d)\vartheta_4(e) \\ + \vartheta_4(b)\vartheta_3(c)\vartheta_2(d)\vartheta_1(e) \end{aligned} \quad (42)$$

(Whittaker and Watson 1990, p. 469).

The complete ELLIPTIC INTEGRALS OF THE FIRST and SECOND KINDS can be expressed using theta functions. Let

$$\xi = \frac{\vartheta_1(z)}{\vartheta_4(z)}, \quad (43)$$

and plug into (36)

$$\left(\frac{d\xi}{dz}\right)^2 = (\vartheta_2^2 - \xi^2 \vartheta_3^2)(\vartheta_3^2 - \xi^2 \vartheta_2^2). \quad (44)$$

Now write

$$\xi \frac{\vartheta_3}{\vartheta_2} \equiv y \quad (45)$$

and

$$z\vartheta_3^2 \equiv u. \quad (46)$$

Then

$$\left(\frac{dy}{du}\right)^2 = (1 - y^2)(1 - k^2 y^2), \quad (47)$$

where the MODULUS is defined by

$$k = k(q) = \frac{\vartheta_2^2(q)}{\vartheta_3^2(q)}. \quad (48)$$

Define also the complementary MODULUS

$$k' = k'(q) = \frac{\vartheta_4^2(-q)}{\vartheta_3^2(q)}. \quad (49)$$

Now, since

$$\vartheta_2^4 + \vartheta_4^4 = \vartheta_3^4, \quad (50)$$

we have shown

$$k^2 + k'^2 = 1. \quad (51)$$

The solution to the equation is

$$y = \frac{\vartheta_3}{\vartheta_2} \frac{\vartheta_1(u\vartheta_3^{-2}|t)}{\vartheta_4(u\vartheta_3^{-2}|t)} \equiv \operatorname{sn}(u, k), \quad (52)$$

which is a JACOBI ELLIPTIC FUNCTION with periods

$$4K(k) = 2\pi\vartheta_3^2(q) \quad (53)$$

and

$$2iK'(k) = \pi t\vartheta_3^2(q). \quad (54)$$

Here,  $K$  is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND,

$$K(k) = \frac{1}{2}\pi\vartheta_3^2(q). \quad (55)$$

## Thomson Lamp Paradox

A lamp is turned on for 1/2 minute, off for 1/4 minute, on for 1/8 minute, etc. At the end of one minute, the lamp switch will have been moved  $\aleph_0$  times, where  $\aleph_0$  is ALEPH-0. Will the lamp be on or off? This PARADOX is actually nonsensical, since it is equivalent to asking if the "last" INTEGER is EVEN or ODD.

## Thomson Problem

Determine the stable equilibrium positions of *N* classical electrons constrained to move on the surface of a SPHERE and repelling each other by an inverse square law. Exact solutions for *N* = 2 to 8 are known, but *N* = 9 and 11 are still unknown.

In reality, Earnshaw's theorem guarantees that no system of discrete electric charges can be held in stable equilibrium under the influence of their electrical interaction alone (Aspden 1987).

#### Thue Constant

The base-2 TRANSCENDENTAL NUMBER

$$0.1101101111101101111\ldots_2,$$

where the  $n$ th bit is 1 if  $n$  is not divisible by 3 and is the complement of the  $(n/3)$ th bit if  $n$  is divisible by 3. It is also given by the SUBSTITUTION MAP

$$0 \rightarrow 111$$

$$1 \rightarrow 110.$$

In decimal, the Thue constant equals 0.8590997969...

see also RABBIT CONSTANT, THUE-MORSE CONSTANT

#### References

#### Thue-Morse Constant

The constant also called the PARITY CONSTANT and defined by

$$P = \frac{1}{2} \sum_{n=0}^{\infty} P(n) 2^{-n} = 0.4124540336401075977\ldots \quad (1)$$

(Sloane's A014571), where  $P(n)$  is the PARITY of  $n$ . Dekking (1977) proved that the Thue-Morse constant is TRANSCENDENTAL, and Allouche and Shallit give a complete proof correcting a minor error of Dekking.

The Thue-Morse constant can be written in base 2 by stages by taking the previous iteration  $a_n$ , taking the complement  $\overline{a_n}$ , and appending, producing

$$\begin{aligned} a_0 &= 0.0_2 \\ a_1 &= 0.01_2 \\ a_2 &= 0.0110_2 \\ a_3 &= 0.01101001_2 \\ a_4 &= 0.0110100110010110_2. \end{aligned} \quad (2)$$

This can be written symbolically as

$$a_{n+1} = a_n + \overline{a_n} \cdot 2^{-2^n} \quad (3)$$

with  $a_0 = 0$ . Here, the complement is the number  $\overline{a_n}$  such that  $a_n + \overline{a_n} = 0.11\ldots_2$ , which can be found from

$$a_n + \overline{a_n} = \sum_{k=1}^{2^n} \left(\frac{1}{2}\right)^k = \frac{1 - \left(\frac{1}{2}\right)^{2^n}}{1 - \frac{1}{2}} - 1 = 1 - 2^{-2^n}. \quad (4)$$

Therefore,

$$\overline{a_n} = 1 - a_n - 2^{-2^n}, \quad (5)$$

and

$$a_{n+1} = a_n + (1 - 2^{-2^n} - a_n)2^{-2^n}. \quad (6)$$

The regular CONTINUED FRACTION for the Thue-Morse constant is [0 2 2 2 1 4 3 5 2 1 4 2 1 5 44 1 4 1 2 4 1 1 5 14 1 50 15 5 1 1 4 2 1 4 1 43 1 4 1 2 1 3 16 1 2 1 2 1 50 1 2 424 1 2 5 2 1 1 1 5 5 2 22 5 1 1 1 1274 3 5 2 1 1 1 4 1 1 15 154 7 2 1 2 2 1 2 1 1 50 1 4 1 2 867374 1 1 1 5 5 1 1 6 1 2 7 2 1650 23 3 1 1 1 2 5 3 84 1 1 1 1284 ...] (Sloane's A014572), and seems to continue with sporadic large terms in suspicious-looking patterns. A nonregular CONTINUED FRACTION is

$$P = \cfrac{1}{3 - \cfrac{1}{2 - \cfrac{1}{4 - \cfrac{1}{16 - \cfrac{15}{256 - \cfrac{255}{65536 - \dots}}}}}}}. \quad (7)$$

A related infinite product is

$$4P = 2 - \frac{1 \cdot 3 \cdot 15 \cdot 255 \cdot 65535 \cdots}{2 \cdot 4 \cdot 16 \cdot 256 \cdot 65536 \cdots}. \quad (8)$$

The SEQUENCE  $a_\infty = 0110100110010110100101100\dots$  (Sloane's A010060) is known as the THUE-MORSE SEQUENCE.

#### Thue-Morse Sequence

The INTEGER SEQUENCE (also called the MORSE-THUE SEQUENCE)

$$01101001100101101001011001101001\dots \quad (1)$$

(Sloane's A010060) which arises in the THUE-MORSE CONSTANT. It can be generated from the SUBSTITUTION MAP

$$0 \rightarrow 01 \quad (2)$$

$$1 \rightarrow 10 \quad (3)$$

starting with 0 as follows:

$$0 \rightarrow 01 \rightarrow 0110 \rightarrow 01101001 \rightarrow \dots \quad (4)$$

Writing the sequence as a POWER SERIES over the GALOIS FIELD GF(2),

$$F(x) = 0 + 1x + 1x^2 + 0x^3 + 1x^4 + \dots, \quad (5)$$

then  $F$  satisfies the quadratic equation

$$(1+x)F^2 + F = \frac{x}{1+x^2} \pmod{2}. \quad (6)$$

This equation has two solutions,  $F$  and  $F'$ , where  $F'$  is the complement of  $F$ , i.e.,

$$F + F' = 1 + x + x^2 + x^3 + \dots = \frac{1}{1+x}, \quad (7)$$

which is consistent with the formula for the sum of the roots of a quadratic. The equality (6) can be demonstrated as follows. Let  $(abcdef\dots)$  be a shorthand for the POWER series

$$a + bx + cx^2 + dx^3 + \dots, \quad (8)$$

so  $F(x)$  is  $(0110100110010110\dots)$ . To get  $F^2$ , simply use the rule for squaring POWER SERIES over GF(2)

$$(A+B)^2 = A^2 + B^2 \pmod{2}, \quad (9)$$

which extends to the simple rule for squaring a POWER SERIES

$$(a_0 + a_1x + a_2x^2 + \dots)^2 = a_0 + a_1x^2 + a_2x^4 + \dots \pmod{2}, \quad (10)$$

i.e., space the series out by a factor of 2,  $(0\ 1\ 1\ 0\ 1\ 0\ 0\ 1\ \dots)$ , and insert zeros in the ODD places to get

$$F^2 = (0010100010000010\dots). \quad (11)$$

Then multiply by  $x$  (which just adds a zero at the front) to get

$$xF^2 = (00010100010000010\dots). \quad (12)$$

Adding to  $F^2$  gives

$$(1+x)F^2 = (0011110011000011\dots). \quad (13)$$

This is the first term of the quadratic equation, which is the Thue-Morse sequence with each term doubled up. The next term is  $F$ , so we have

$$(1+x)F^2 = (0011110011000011\dots) \quad (14)$$

$$F = (0110100110010110\dots). \quad (15)$$

The sum is the above two sequences XORed together (there are no CARRIES because we're working over GF(2)), giving

$$(1+x)F^2 + F = (01010101010101\dots). \quad (16)$$

We therefore have

$$(1+x)F^2 + F = \frac{x}{1+x^2} \\ = x + x^3 + x^5 + x^7 + x^9 + x^{11} + \dots \pmod{2}. \quad (17)$$

The Thue-Morse sequence is an example of a cube-free sequence on two symbols (Morse and Hedlund 1944), i.e., it contains no substrings of the form  $WWW$ , where  $W$  is any WORD. For example, it does not contain the WORDS 000, 010101 or 010010010. In fact, the following stronger statement is true: the Thue-Morse sequence does not contain any substrings of the form  $WWa$ , where  $a$  is the first symbol of  $W$ . We can obtain a SQUAREFREE sequence on three symbols by doing the following: take the Thue-Morse sequence 0110100110010110... and look at the sequence of WORDS of length 2 that appear: 01 11 10 01 10 00 01 11 10 .... Replace 01 by 0, 10 by 1, 00 by 2 and 11 by 2 to get the following: 021012021.... Then this SEQUENCE is SQUAREFREE (Morse and Hedlund 1944).

The Thue-Morse sequence has important connections with the GRAY CODE. Kindermann generates fractal music using the SELF-SIMILARITY of the Thue-Morse sequence.

#### Thurston's Geometrization Conjecture

Thurston's conjecture has to do with geometric structures on 3-D MANIFOLDS. Before stating Thurston's conjecture, some background information is useful. 3-dimensional MANIFOLDS possess what is known as a standard 2-level DECOMPOSITION. First, there is the CONNECTED SUM DECOMPOSITION, which says that every COMPACT 3-MANIFOLD is the CONNECTED SUM of a unique collection of PRIME 3-MANIFOLDS.

The second DECOMPOSITION is the JACO-SHALEN-JOHANNSSON TORUS DECOMPOSITION, which states that irreducible orientable COMPACT 3-MANIFOLDS have a canonical (up to ISOTOPY) minimal collection of disjointly EMBEDDED incompressible TORI such that each component of the 3-MANIFOLD removed by the TORI is either "atoroidal" or "Seifert-fibered."

Thurston's conjecture is that, after you split a 3-MANIFOLD into its CONNECTED SUM and then JACO-SHALEN-JOHANNSSON TORUS DECOMPOSITION, the remaining components each admit exactly one of the following geometries:

1. EUCLIDEAN GEOMETRY,
2. HYPERBOLIC GEOMETRY,
3. SPHERICAL GEOMETRY,
4. the GEOMETRY of  $S^2 \times \mathbb{R}$ ,
5. the GEOMETRY of  $\mathbb{H}^2 \times \mathbb{R}$ ,
6. the GEOMETRY of  $SL_2\mathbb{R}$ ,
7. NIL GEOMETRY, or
8. SOL GEOMETRY.

Here,  $S^2$  is the 2-SPHERE and  $H^2$  is the HYPERBOLIC PLANE. If Thurston's conjecture is true, the truth of the POINCARÉ CONJECTURE immediately follows.

see also CONNECTED SUM DECOMPOSITION, EUCLIDEAN GEOMETRY, HYPERBOLIC GEOMETRY, JACOSHALEN-JOHANSSON TORUS DECOMPOSITION, NIL GEOMETRY, POINCARÉ CONJECTURE, SOL GEOMETRY, SPHERICAL GEOMETRY

## Thwaites Conjecture

see COLLATZ PROBLEM

## Tic-Tac-Toe

The usual game of tic-tac-toe (also called TICKTACKTOE) is 3-in-a-row on a  $3 \times 3$  board. However, a generalized  $n$ -IN-A-ROW on an  $n \times m$  board can also be considered. For  $n = 1$  and 2 the first player can always win. If the board is at least  $3 \times 4$ , the first player can win for  $n = 3$ .

However, for TIC-TAC-TOE which uses a  $3 \times 3$  board, a draw can always be obtained. If the board is at least  $4 \times 30$ , the first player can win for  $n = 4$ . For  $n = 5$ , a draw can always be obtained on a  $5 \times 5$  board, but the first player can win if the board is at least  $15 \times 15$ . The cases  $n = 6$  and 7 have not yet been fully analyzed for an  $n \times n$  board, although draws can always be forced for  $n = 8$  and 9. On an  $\infty \times \infty$  board, the first player can win for  $n = 1, 2, 3$ , and 4, but a tie can always be forced for  $n \geq 8$ . For  $3 \times 3 \times 3$  and  $4 \times 4 \times 4$ , the first player can always win (Gardner 1979).

## Tightly Embedded

$Q$  is said to be tightly embedded if  $|Q \cap Q^g|$  is ODD for all  $g \in G - N_G(Q)$ , where  $N_G(Q)$  is the NORMALIZER of  $Q$  in  $G$ .

## Tiling

A plane-filling arrangement of plane figures or its generalization to higher dimensions. Formally, a tiling is a collection of disjoint open sets, the closures of which cover the plane. Given a single tile, the so-called first CORONA is the set of all tiles that have a common boundary point with the tile (including the original tile itself).

WANG'S CONJECTURE (1961) stated that if a set of tiles tiled the plane, then they could always be arranged to do so periodically. A periodic tiling of the PLANE by POLYGONS or SPACE by POLYHEDRA is called a TESSELLATION. The conjecture was refuted in 1966 when R. Berger showed that an aperiodic set of 20,426 tiles exists. By 1971, R. Robinson had reduced the number to six and, in 1974, R. Penrose discovered an aperiodic set (when color-matching rules are included) of two tiles: the so-called PENROSE TILES. (Penrose also sued the Kimberly Clark Corporation over their quilted toilet paper, which allegedly resembles a Penrose aperiodic tiling; Mirsky 1997.)

It is not known if there is a single aperiodic tile.

$n$ -gon	tilings
3	any
4	any
5	14
6	3

The number of tilings possible for convex irregular POLYGONS are given in the above table. Any TRIANGLE or convex QUADRILATERAL tiles the plane. There are at least 14 classes of convex PENTAGONAL tilings. There are at least three aperiodic tilings of HEXAGONS, given by the following types:

$$\begin{aligned} A + B + C &= 360^\circ & a &= d \\ A + B + D &= 360^\circ & a &= d, c = e \\ A &= C = E & a &= b, c = d, e = f \end{aligned} \quad (1)$$

(Gardner 1988). Note that the periodic hexagonal TESSELLATION is a degenerate case of all three tilings with

$$A = B = C = D = E = F \quad a = b = c = d = e = f. \quad (2)$$

There are no tilings for convex  $n$ -gons for  $n \geq 7$ .

### Tiling Theorem

Due to Lebesgue and Brouwer. If an  $n$ -D figure is covered in any way by sufficiently small subregions, then there will exist points which belong to at least  $n + 1$  of these subareas. Moreover, it is always possible to find a covering by arbitrarily small regions for which no point will belong to more than  $n + 1$  regions.

see also TESSELLATION, TILING

### Times

The operation of MULTIPLICATION, i.e.,  $a$  times  $b$ . Various notations are  $a \times b$ ,  $a \cdot b$ ,  $ab$ , and  $(a)(b)$ . The "multiplication sign"  $\times$  is based on SAINT ANDREW'S CROSS (Bergamini 1969). Floating point MULTIPLICATION is sometimes denoted  $\otimes$ .

### Titanic Prime

A PRIME with  $\geq 1000$  DIGITS. As of 1990, there were more than 1400 known (Ribenoim 1990). The table below gives the number of known titanic primes as a function of year end.

Year	Titanic Primes
1992	2254
1993	9166
1994	9779
1995	12391

### Titchmarsh Theorem

If  $f(\omega)$  is SQUARE INTEGRABLE over the REAL  $\omega$  axis, then any one of the following implies the other two:

1. The FOURIER TRANSFORM of  $f(\omega)$  is 0 for  $t < 0$ .
2. Replacing  $\omega$  by  $z$ , the function  $f(z)$  is analytic in the COMPLEX PLANE  $z$  for  $y > 0$  and approaches  $f(x)$  almost everywhere as  $y \rightarrow 0$ . Furthermore,  $\int_{-\infty}^{\infty} |f(x+iy)|^2 dx < k$  for some number  $k$  and  $y > 0$  (i.e., the integral is bounded).
3. The REAL and IMAGINARY PARTS of  $f(z)$  are HILBERT TRANSFORMS of each other.

### Tits Group

A finite SIMPLE GROUP which is a SUBGROUP of the TWISTED CHEVALLEY GROUP  ${}^2F_4(2)$ .

### Toeplitz Matrix

Given  $2N - 1$  numbers  $r_k$  where  $k = -N + 1, \dots, -1, 0, 1, \dots, N - 1$ , a MATRIX of the form

$$\begin{bmatrix} r_0 & r_{-1} & r_{-2} & \cdots & r_{-n+1} \\ r_1 & r_0 & r_{-1} & \cdots & r_{-n+2} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ r_{n-1} & r_{n-2} & r_{n-3} & \cdots & r_0 \end{bmatrix}$$

is called a Toeplitz matrix. MATRIX equations of the form

$$\sum_{j=1}^N r_{i-j} x_j = y_i$$

can be solved with  $\mathcal{O}(N^2)$  operations.

### Togliatti Surface

Togliatti (1940, 1949) showed that QUINTIC SURFACES having 31 ORDINARY DOUBLE POINTS exist, although he did not explicitly derive equations for such surfaces. Beauville (1978) subsequently proved that 31 double points are the maximum possible, and quintic surfaces having 31 ORDINARY DOUBLE POINTS are therefore sometimes called Togliatti surfaces. van Straten (1993) subsequently constructed a 3-D family of solutions and in 1994, Barth derived the example known as the DERVISH.

### Tomography

Tomography is the study of the reconstruction of 2- and 3-dimensional objects from 1-dimensional slices. The RADON TRANSFORM is an important tool in tomography.

Rather surprisingly, there exist certain sets of four directions in Euclidean  $n$ -space such that X-rays of a convex body in these directions distinguish it from all other convex bodies.

### Topological Basis

A topological basis is a SUBSET  $B$  of a SET  $T$  in which all other OPEN SETS can be written as UNIONS or finite INTERSECTIONS of  $B$ . For the REAL NUMBERS, the SET of all OPEN INTERVALS is a basis.

### Topological Completion

The topological completion  $C$  of a FIELD  $F$  with respect to the ABSOLUTE VALUE  $|\cdot|$  is the smallest FIELD containing  $F$  for which all CAUCHY SEQUENCES or rationals converge.

### Topologically Conjugate

Two MAPS  $\phi, \psi : M \rightarrow M$  are said to be topologically conjugate if there EXISTS a HOMEOMORPHISM  $h : M \rightarrow M$  such that  $\phi \circ h = h \circ \psi$ , i.e.,  $h$  maps  $\psi$ -orbits onto  $\phi$ -orbits. Two maps which are topologically conjugate cannot be distinguished topologically.

see also ANOSOV DIFFEOMORPHISM, STRUCTURALLY STABLE

### Topological Dimension

see LEBESGUE COVERING DIMENSION

### Topological Entropy

The topological entropy of a MAP  $M$  is defined as

$$h_T(M) = \sup_{\{W_i\}} h(M, \{W_i\}),$$

where  $\{W_i\}$  is a partition of a bounded region  $W$  containing a probability measure which is invariant under  $M$ , and sup is the SUPREMUM.

**Topological Groupoid**

A topological groupoid over  $B$  is a GROUPOID  $G$  such that  $B$  and  $G$  are TOPOLOGICAL SPACES and  $\alpha, \beta$ , and multiplication are continuous maps. Here,  $\alpha$  and  $\beta$  are maps from  $G$  onto  $\mathbb{R}^2$  with  $\alpha : (x, \gamma, y) \mapsto x$  and  $\beta : (x, \gamma, y) \mapsto y$ .

References

Weinstein, A. "Groupoids: Unifying Internal and External Symmetry." *Not. Amer. Math. Soc.* **43**, 744–752, 1996.

**Topological Manifold**

A TOPOLOGICAL SPACE  $M$  satisfying some separability (i.e., it is a HAUSDORFF SPACE) and countability (i.e., it is a PARACOMPACT SPACE) conditions such that every point  $p \in M$  has a NEIGHBORHOOD homeomorphic to an OPEN SET in  $\mathbb{R}^n$  for some  $n \geq 0$ . Every SMOOTH MANIFOLD is a topological manifold, but not necessarily vice versa. The first nonsmooth topological manifold occurs in 4-D.

Nonparacompact manifolds are of little use in mathematics, but non-Hausdorff manifolds do occasionally arise in research (Hawking and Ellis 1975). For manifolds, Hausdorff and second countable are equivalent to Hausdorff and paracompact, and both are equivalent to the manifold being embeddable in some large-dimensional Euclidean space.

**Topological Vector Space**

A TOPOLOGICAL SPACE such that the two algebraic operations of VECTOR SPACE are continuous in the topology.

References

Köthe, G. *Topological Vector Spaces*. New York: Springer-Verlag, 1979.

**Topologically Transitive**

A FUNCTION  $f$  is topologically transitive if, given any two intervals  $U$  and  $V$ , there is some POSITIVE INTEGER  $k$  such that  $f^k(U) \cap V = \emptyset$ . Vaguely, this means that neighborhoods of points eventually get flung out to "big" sets so that they don't necessarily stick together in one localized clump.

see also CHAOS

**Topology**

Topology is the mathematical study of properties of objects which are preserved through deformations, twistings, and stretchings. (Tearing, however, is not allowed.) A CIRCLE is topologically equivalent to an ELLIPSE (into which it can be deformed by stretching) and a SPHERE is equivalent to an ELLIPSOID. Continuing along these lines, the SPACE of all positions of the minute hand on a clock is topologically equivalent to a CIRCLE (where SPACE of all positions means "the collection of all positions"). Similarly, the SPACE of all positions of the minute and hour hands is equivalent to a TORUS. The SPACE of all positions of the hour, minute and second hands form a 4-D object that cannot be visualized quite as simply as the former objects since it cannot be placed in our 3-D world, although it can be visualized by other means.

There is more to topology, though. Topology began with the study of curves, surfaces, and other objects in the plane and 3-space. One of the central ideas in topology is that spatial objects like CIRCLES and SPHERES can be treated as objects in their own right, and knowledge of objects is independent of how they are "represented" or "embedded" in space. For example, the statement "if you remove a point from a CIRCLE, you get a line segment" applies just as well to the CIRCLE as to an ELLIPSE, and even to tangled or knotted CIRCLES, since the statement involves only topological properties.

Topology has to do with the study of spatial objects such as curves, surfaces, the space we call our universe, the space-time of general relativity, fractals, knots, manifolds (objects with some of the same basic spatial properties as our universe), phase spaces that are encountered in physics (such as the space of hand-positions of a clock), symmetry groups like the collection of ways of rotating a top, etc.

The "objects" of topology are often formally defined as TOPOLOGICAL SPACES. If two objects have the same topological properties, they are said to be HOMEOMORPHIC (although, strictly speaking, properties that are not destroyed by stretching and distorting an object are really properties preserved by ISOTOPY, not HOMEOMORPHISM; ISOTOPY has to do with distorting embedded objects, while HOMEOMORPHISM is intrinsic).

Topology is divided into ALGEBRAIC TOPOLOGY (also called COMBINATORIAL TOPOLOGY), DIFFERENTIAL TOPOLOGY, and LOW-DIMENSIONAL TOPOLOGY.

There is also a formal definition for a topology defined in terms of set operations. A SET  $X$  along with a collection  $T$  of SUBSETS of it is said to be a topology if the SUBSETS in  $T$  obey the following properties:

1. The (trivial) subsets  $X$  and the EMPTY SET  $\emptyset$  are in  $T$ .
2. Whenever sets  $A$  and  $B$  are in  $T$ , then so is  $A \cap B$ .
3. Whenever two or more sets are in  $T$ , then so is their UNION

(Bishop and Goldberg 1980).

A SET  $X$  for which a topology  $T$  has been specified is called a TOPOLOGICAL SPACE (Munkres 1975, p. 76). For example, the SET  $X = \{0, 1, 2, 3\}$  together with the SUBSETS  $T = \{0\}, \{1, 2, 3\}, \emptyset, \{0, 1, 2, 3\}$  comprises a topology, and  $X$  is a TOPOLOGICAL SPACE.

Topologies can be built up from TOPOLOGICAL BASES. For the REAL NUMBERS, the topology is the UNION of OPEN INTERVALS.

#### Toric Variety

Let  $m_1, m_2, \dots, m_n$  be distinct primitive elements of a 2-D LATTICE  $M$  such that  $\det(m_i, m_{i+1}) > 0$  for  $i = 1, \dots, n$ . Each collection  $\Gamma = \{m_1, m_2, \dots, m_n\}$  then forms a set of rays of a unique complete fan in  $M$ , and therefore determines a 2-D toric variety  $X_\Gamma$ .

#### Torispherical Dome

A torispherical dome is the surface obtained from the intersection of a SPHERICAL CAP with a tangent TORUS, as illustrated above. The radius of the sphere  $R$  is called

the "crown radius," and the radius of the torus is called the "knuckle radius." Torispherical domes are used to construct pressure vessels.

see also DOME, SPHERICAL CAP

### Torn Square Fractal

see CESÀRO FRACTAL

### Toroid

A SURFACE OF REVOLUTION obtained by rotating a closed PLANE CURVE about an axis parallel to the plane which does not intersect the curve. The simplest toroid is the TORUS.

see also PAPPUS'S CENTROID THEOREM, SURFACE OF REVOLUTION, TORUS

### Toroidal Coordinates

A system of CURVILINEAR COORDINATES for which several different notations are commonly used. In this work ( $u, v, \phi$ ) is used, whereas Arfken (1970) uses ( $\xi, \eta, \varphi$ ). The toroidal coordinates are defined by

$$x = \frac{a \sinh v \cos \phi}{\cosh v - \cos u} \quad (1)$$

$$y = \frac{a \sinh v \sin \phi}{\cosh v - \cos u} \quad (2)$$

$$z = \frac{a \sin u}{\cosh v - \cos u}, \quad (3)$$

where  $\sinh z$  is the HYPERBOLIC SINE and  $\cosh z$  is the HYPERBOLIC COSINE. The SCALE FACTORS are

$$h_u = \frac{a}{\cosh v - \cos u} \quad (4)$$

$$h_v = \frac{a}{\cosh v - \cos u} \quad (5)$$

$$h_\phi = \frac{a \sinh v}{\cosh v - \cos u}. \quad (6)$$

The LAPLACIAN is

$$\begin{aligned} \nabla^2 f &= \frac{(\cosh v - \cos u)^3}{a^2} \frac{\partial}{\partial u} \left( \frac{1}{\cosh v - \cos u} \frac{\partial f}{\partial u} \right) \\ &+ \frac{(\cosh v - \cos u)^3}{a^2 \sinh v} \frac{\partial}{\partial v} \left( \frac{\sinh v}{\cosh v - \cos u} \frac{\partial f}{\partial v} \right) \\ &+ \frac{(\cosh v - \cos u)^2}{a^2 \sinh v} \frac{\partial^2 f}{\partial \phi^2} \\ &= \left( \frac{-3 \cos \coth^2 v + \cosh v \coth^2 v}{\cosh v - \cos u} \right. \\ &\quad \left. + \frac{+3 \cos^2 u \coth v \operatorname{csch} v - \cos^3 u \operatorname{csch}^2 v}{\cosh v - \cos u} \right) \frac{\partial^2}{\partial \phi^2} \\ &+ (\cos u - \cosh v) \sin u \frac{\partial}{\partial u} + (\cosh v - \cos u)^2 \frac{\partial^2}{\partial u^2} \\ &+ (\cosh v - \cos u) (\cosh v \coth v - \sinh v \\ &\quad - \cos u \coth v) \frac{\partial}{\partial v} + (\cosh^2 v - \cos u)^2 \frac{\partial^2}{\partial v^2}. \end{aligned} \quad (7)$$

The HELMHOLTZ DIFFERENTIAL EQUATION is not separable in toroidal coordinates, but LAPLACE'S EQUATION is.

**Toroidal Function**

A class of functions also called RING FUNCTIONS which appear in systems having toroidal symmetry. Toroidal functions can be expressed in terms of the LEGENDRE FUNCTIONS and SECOND KINDS (Abramowitz and Stegun 1972, p. 336):

$$P_{\nu-1/2}^{\mu}(\cosh \eta) = [\Gamma(1-\mu)]^{-1} 2^{2\mu} (1-e^{-2\eta})^{-\mu} e^{-(\nu+1/2)\eta} \\ \times {}_2F_1\left(\frac{1}{2}-\mu, \frac{1}{2}+\nu-\mu; 1-2\mu; 1-e^{-2\eta}\right) \\ P_{n-1/2}^m(\cosh \eta) = \frac{\Gamma(n+m+\frac{1}{2})(\sinh \eta)^m}{\Gamma(n-m+\frac{1}{2})2^m\sqrt{\pi}\Gamma(m+\frac{1}{2})} \\ \times \int_0^{\pi} \frac{\sin^{2m}\phi d\phi}{(\cosh \eta + \cos \phi \sinh \eta)^{n+m+1/2}} \\ Q_{\nu-1/2}^{\mu}(\cosh \eta) = [\Gamma(1+\nu)]^{-1} \sqrt{\pi} e^{i\mu\pi} \Gamma\left(\frac{1}{2}+\nu+\mu\right) \\ \times (1-e^{-2\eta})^{\mu} e^{-(\nu+1/2)\eta} {}_2F_1\left(\frac{1}{2}-\mu, \frac{1}{2}+\nu+\mu; 1+\mu; 1-e^{-2\eta}\right) \\ Q_{n-1/2}^m(\cosh \eta) = \frac{(-1)^m \Gamma(n+\frac{1}{2})}{\Gamma(n-m+\frac{1}{2})} \\ \times \int_0^{\infty} \frac{\cosh(mt) dt}{(\cosh \eta + \cosh t \sinh \eta)^{n+1/2}}$$

for  $n > m$ . Byerly (1959) identifies

$$\frac{1}{i^{n/2}} P_m^n(\coth x) = \operatorname{csch}^n x \frac{d^n P_m(\coth x)}{d(\coth x)^n}$$

as a TOROIDAL HARMONIC.

**Toroidal Harmonic**

see TOROIDAL FUNCTION

**Toroidal Polyhedron**

A toroidal polyhedron is a POLYHEDRON with GENUS  $g \geq 1$  (i.e., having one or more HOLES). Examples of toroidal polyhedra include the CSÁSZÁR POLYHEDRON and SZILASSI POLYHEDRON, both of which have GENUS 1 (i.e., the TOPOLOGY of a TORUS).

The only known TOROIDAL POLYHEDRON with no DIAGONALS is the CSÁSZÁR POLYHEDRON. If another exists, it must have 12 or more VERTICES and GENUS  $g \geq 6$ . The smallest known single-hole toroidal POLYHEDRON made up of only EQUILATERAL TRIANGLES is composed of 48 of them.

**Torricelli Point**

see FERMAT POINT

**Torsion (Differential Geometry)**

The rate of change of the OSCULATING PLANE of a SPACE CURVE. The torsion  $\tau$  is POSITIVE for a right-handed curve, and NEGATIVE for a left-handed curve. A curve with CURVATURE  $\kappa \neq 0$  is planar IFF  $\tau = 0$ .

The torsion can be defined by

$$\tau \equiv -\mathbf{N} \cdot \mathbf{B}',$$

where  $\mathbf{N}$  is the unit NORMAL VECTOR and  $\mathbf{B}$  is the unit BINORMAL VECTOR. Written explicitly in terms of a parameterized VECTOR FUNCTION  $\mathbf{x}$ ,

$$\tau = \frac{|\dot{\mathbf{x}} \ddot{\mathbf{x}} \ddot{\mathbf{x}}|}{\dot{\mathbf{x}} \cdot \dot{\mathbf{x}}} = \rho^2 |\ddot{\mathbf{x}} \ddot{\mathbf{x}}|,$$

where  $|\mathbf{a} \mathbf{b} \mathbf{c}|$  denotes a SCALAR TRIPLE PRODUCT and  $\rho$  is the RADIUS OF CURVATURE. The quantity  $1/\tau$  is called the RADIUS OF TORSION and is denoted  $\sigma$  or  $\phi$ .

**Torsion (Group Theory)**

If  $G$  is a GROUP, then the torsion elements  $\text{Tor}(G)$  of  $G$  (also called the torsion of  $G$ ) are defined to be the set of elements  $g$  in  $G$  such that  $g^n = e$  for some NATURAL NUMBER  $n$ , where  $e$  is the IDENTITY ELEMENT of the GROUP  $G$ .

In the case that  $G$  is ABELIAN,  $\text{Tor}(G)$  is a SUBGROUP and is called the torsion subgroup of  $G$ . If  $\text{Tor}(G)$  consists only of the IDENTITY ELEMENT, the GROUP  $G$  is called torsion-free.

see also ABELIAN GROUP, GROUP, IDENTITY ELEMENT

**Torsion Number**

One of a set of numbers defined in terms of an invariant generated by the finite cyclic covering spaces of a KNOT complement. The torsion numbers for KNOTS up to 9 crossings were cataloged by Reidemeister (1948).

**Torsion Tensor**

The TENSOR defined by

$$T^l_{jk} \equiv -(\Gamma^l_{jk} - \Gamma^l_{kj}),$$

where  $\Gamma^l_{jk}$  are CONNECTION COEFFICIENTS.

see also CONNECTION COEFFICIENT

**Torus**

A torus is a surface having GENUS 1, and therefore possessing a single "HOLE." The usual torus in 3-D space is shaped like a donut, but the concept of the torus is extremely useful in higher dimensional space as well. One of the more common uses of  $n$ -D tori is in DYNAMICAL SYSTEMS. A fundamental result states that the PHASE SPACE trajectories of a HAMILTONIAN SYSTEM with  $n$  DEGREES OF FREEDOM and possessing  $n$  INTEGRALS OF MOTION lie on an  $n$ -D MANIFOLD which is topologically equivalent to an  $n$ -torus (Tabor 1989).

The usual 3-D "ring" torus is known in older literature as an "ANCHOR RING." Let the radius from the center of the hole to the center of the torus tube be  $c$ , and the

radius of the tube be  $a$ . Then the equation in CARTESIAN COORDINATES is

$$(c - \sqrt{x^2 + y^2})^2 + z^2 = a^2. \quad (1)$$

The parametric equations of a torus are

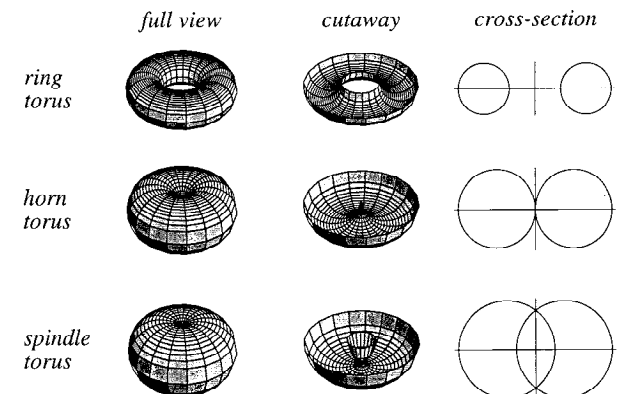

$$x = (c + a \cos v) \cos u \quad (2)$$

$$y = (c + a \cos v) \sin u \quad (3)$$

$$z = a \sin v \quad (4)$$

for  $u, v \in [0, 2\pi)$ . Three types of torus, known as the STANDARD TORI, are possible, depending on the relative sizes of  $a$  and  $c$ .  $c > a$  corresponds to the RING TORUS (shown above),  $c = a$  corresponds to a HORN TORUS which is tangent to itself at the point  $(0, 0, 0)$ , and  $c < a$  corresponds to a self-intersecting SPINDLE TORUS (Pinkall 1986).

If no specification is made, "torus" is taken to mean RING TORUS. The three STANDARD TORI are illustrated below, where the first image shows the full torus, the second a cut-away of the bottom half, and the third a CROSS-SECTION of a plane passing through the  $z$ -AXIS.

The STANDARD TORI and their inversions are CYCLIDES. If the coefficient of  $\sin v$  in the formula for  $z$  is changed to  $b \neq a$ , an ELLIPTIC TORUS results.

To compute the metric properties of the ring torus, define the inner and outer radii by

$$r \equiv c - a \quad (5)$$

$$R \equiv c + a. \quad (6)$$

Solving for  $a$  and  $c$  gives

$$a = \frac{1}{2}(R - r) \quad (7)$$

$$c = \frac{1}{2}(R + r). \quad (8)$$

Then the SURFACE AREA of this torus is

$$S = (2\pi a)(2\pi c) = 4\pi^2 ac \quad (9)$$

$$= \pi^2(R + r)(R - r), \quad (10)$$

and the VOLUME can be computed from PAPPUS'S CENTROID THEOREM

$$V = (\pi a^2)^2 \pi c = 2\pi^2 a^2 c \quad (11)$$

$$= \frac{1}{4}\pi^2(R + r)(R - r)^2. \quad (12)$$

The coefficients of the first and second FUNDAMENTAL FORMS of the torus are given by

$$e = -(c + a \cos v) \cos v \quad (13)$$

$$f = 0 \quad (14)$$

$$g = -a \quad (15)$$

$$E = (c + a \cos v)^2 \quad (16)$$

$$F = 0 \quad (17)$$

$$G = a^2, \quad (18)$$

giving RIEMANNIAN METRIC

$$ds^2 = (c + a \cos v)^2 du^2 + a^2 dv^2, \quad (19)$$

AREA ELEMENT

$$dA = a(c + a \cos v) du \wedge dv \quad (20)$$

(where  $du \wedge dv$  is a WEDGE PRODUCT), and GAUSSIAN and MEAN CURVATURES as

$$K = \frac{\cos v}{a(c + a \cos v)} \quad (21)$$

$$H = -\frac{c + 2a \cos v}{2a(c + a \cos v)} \quad (22)$$

(Gray 1993, pp. 289–291).

A torus with a HOLE in its surface can be turned inside out to yield an identical torus. A torus can be knotted externally or internally, but not both. These two cases are AMBIENT ISOTOPIES, but not REGULAR ISOTOPIES. There are therefore three possible ways of embedding a torus with zero or one KNOT.

An arbitrary point  $P$  on a torus (not lying in the  $xy$ -plane) can have four CIRCLES drawn through it. The first circle is in the plane of the torus and the second is PERPENDICULAR to it. The third and fourth CIRCLES are called VILLARCEAU CIRCLES (Villarceau 1848, Schmidt 1950, Coxeter 1969, Melnick 1983).

To see that two additional CIRCLES exist, consider a coordinate system with origin at the center of torus, with  $\hat{z}$  pointing up. Specify the position of  $P$  by its ANGLE  $\phi$  measured around the tube of the torus. Define  $\phi = 0$  for the circle of points farthest away from the center of the torus (i.e., the points with  $x^2 + y^2 = R^2$ ), and draw the  $x$ -AXIS as the intersection of a plane through the  $z$ -axis and passing through  $P$  with the  $xy$ -plane. Rotate about the  $y$ -AXIS by an ANGLE  $\theta$ , where

$$\theta = \sin^{-1} \left( \frac{a}{c} \right). \quad (23)$$

In terms of the old coordinates, the new coordinates are

$$x = x_1 \cos \theta - z_1 \sin \theta \quad (24)$$

$$z = x_1 \sin \theta + z_1 \cos \theta. \quad (25)$$

So in  $(x_1, y_1, z_1)$  coordinates, equation (1) of the torus becomes

$$[\sqrt{(x_1 \cos \theta - z_1 \sin \theta)^2 + y_1^2} - c]^2 + (x_1 \sin \theta + z_1 \cos \theta)^2 = a^2. \quad (26)$$

Squaring both sides gives

$$(x_1 \cos \theta - z_1 \sin \theta)^2 + y_1^2 + c^2 - 2c\sqrt{(x_1 \cos \theta - z_1 \sin \theta)^2 + y_1^2} + (x_1 \sin \theta + z_1 \cos \theta)^2 = a^2. \quad (27)$$

But

$$(x_1 \cos \theta - z_1 \sin \theta)^2 + (x_1 \sin \theta + z_1 \cos \theta)^2 = x_1^2 + z_1^2, \quad (28)$$

so

$$x_1^2 + y_1^2 + z_1^2 + c^2 - 2c\sqrt{(x_1 \cos \theta - z_1 \sin \theta)^2 + y_1^2} = a^2. \quad (29)$$

In the  $z_1 = 0$  plane, plugging in (23) and factoring gives

$$[x_1^2 + (y_1 - a)^2 - c^2][x_1^2 + (y_1 + a)^2 - c^2] = 0. \quad (30)$$

This gives the CIRCLES

$$x_1^2 + (y_1 - a)^2 = c^2 \quad (31)$$

and

$$x_1^2 + (y_1 + a)^2 = c^2 \quad (32)$$

in the  $z_1$  plane. Written in MATRIX form with parameter  $t \in [0, 2\pi)$ , these are

$$C_1 = \begin{bmatrix} c \cos t \\ c \sin t + a \\ 0 \end{bmatrix} \quad (33)$$

$$C_2 = \begin{bmatrix} c \cos t \\ c \sin t - a \\ 0 \end{bmatrix}. \quad (34)$$

In the original  $(x, y, z)$  coordinates,

$$\begin{aligned} C_1 &= \begin{bmatrix} \cos \theta & 0 & -\sin \theta \\ 0 & 1 & 0 \\ -\sin \theta & 0 & \cos \theta \end{bmatrix} \begin{bmatrix} c \cos t \\ c \sin t + a \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} c \cos \theta \cos t \\ c \sin t + a \\ -c \sin \theta \cos t \end{bmatrix} \end{aligned} \quad (35)$$

$$\begin{aligned} C_2 &= \begin{bmatrix} \cos \theta & 0 & \sin \theta \\ 0 & 1 & 0 \\ -\sin \theta & 0 & \cos \theta \end{bmatrix} \begin{bmatrix} c \cos t \\ c \sin t - a \\ 0 \end{bmatrix} \\ &= \begin{bmatrix} c \cos \theta \cos t \\ c \sin t - a \\ -c \sin \theta \cos t \end{bmatrix}. \end{aligned} \quad (36)$$

The point  $P$  must satisfy

$$z = a \sin \phi = c \sin \theta \cos t, \quad (37)$$

so

$$\cos t = \frac{a \sin \phi}{c \sin \theta}. \quad (38)$$

Plugging this in for  $x_1$  and  $y_1$  gives the ANGLE  $\psi$  by which the CIRCLE must be rotated about the  $z$ -AXIS in order to make it pass through  $P$ ,

$$\psi = \tan^{-1} \left( \frac{y}{x} \right) = \frac{c \sin t + a}{c \cos \theta \cos t} = \frac{c \sqrt{1 - \cos^2 t} + a}{c \cos \theta \cos t}. \quad (39)$$

The four CIRCLES passing through  $P$  are therefore

$$C_1 = \begin{bmatrix} \cos \psi & \sin \psi & 0 \\ -\sin \psi & \cos \psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} c \cos \theta \cos t \\ c \sin t + a \\ -c \sin \theta \cos t \end{bmatrix} \quad (40)$$

$$C_2 = \begin{bmatrix} \cos \psi & \sin \psi & 0 \\ -\sin \psi & \cos \psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} c \cos \theta \cos t \\ c \sin t - a \\ -c \sin \theta \cos t \end{bmatrix} \quad (41)$$

$$C_3 = \begin{bmatrix} (c + a \cos \phi) \cos t \\ (c + a \cos \phi) \sin t \\ a \sin \phi \end{bmatrix} \quad (42)$$

$$C_4 = \begin{bmatrix} c + a \cos t \\ 0 \\ a \sin t \end{bmatrix}. \quad (43)$$

#### Torus Coloring

The number of colors SUFFICIENT for MAP COLORING on a surface of GENUS  $g$  is given by the HEAWOOD CONJECTURE,

$$\chi(g) = \left\lfloor \frac{1}{2}(7 + \sqrt{48g + 1}) \right\rfloor,$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. The fact that  $\chi(g)$  (which is called the CHROMATIC NUMBER) is also NECESSARY was proved by Ringel and Youngs (1968) with two exceptions: the SPHERE (which requires the same number of colors as the PLANE) and the KLEIN BOTTLE. A  $g$ -holed TORUS therefore requires  $\chi(g)$  colors. For  $g = 0, 1, \dots$ , the first few values of  $\chi(g)$  are 4, 7, 8, 9, 10, 11, 12, 12, 13, 13, 14, 15, 15, 16, ... (Sloane's A000934).

**Torus Cutting**

With  $n$  cuts of a TORUS of GENUS 1, the maximum number of pieces which can be obtained is

$$N(n) = \frac{1}{6}(n^3 + 3n^2 + 8n).$$

The first few terms are 2, 6, 13, 24, 40, 62, 91, 128, 174, 230, ... (Sloane's A003600).

**Torus Knot**

A  $(p, q)$ -torus KNOT is obtained by looping a string through the HOLE of a TORUS  $p$  times with  $q$  revolutions before joining its ends, where  $p$  and  $q$  are RELATIVELY PRIME. A  $(p, q)$ -torus knot is equivalent to a  $(q, p)$ -torus knot. The CROSSING NUMBER of a  $(p, q)$ -torus knot is

$$c = \min\{p(q-1), q(p-1)\} \quad (1)$$

(Murasugi 1991). The UNKNOTTING NUMBER of a  $(p, q)$ -torus knot is

$$u = \frac{1}{2}(p-1)(q-1) \quad (2)$$

(Adams 1991).

Torus knots with fewer than 11 crossings are the TREFOIL KNOT 03<sub>001</sub> (3, 2), SOLOMON'S SEAL KNOT 05<sub>001</sub> (5, 2), 07<sub>001</sub> (7, 2), 08<sub>019</sub> (4, 3), 09<sub>001</sub> (9, 2), and 10<sub>124</sub> (5, 3) (Adams *et al.* 1991). The only KNOTS which are not HYPERBOLIC KNOTS are torus knots and SATELLITE KNOTS (including COMPOSITE KNOTS). The (2,  $q$ ), (3, 4), and (3, 5)-torus knots are ALMOST ALTERNATING KNOTS.

The JONES POLYNOMIAL of an  $(m, n)$ -TORUS KNOT is

$$\frac{t^{(m-1)(n-1)/2}(1 - t^{m+1} - t^{n+1} + t^{m+n})}{1 - t^2}. \quad (3)$$

The BRACKET POLYNOMIAL for the torus knot  $K_n = (2, n)$  is given by the RECURRENCE RELATION

$$\langle K_n \rangle = A \langle K_{n-1} \rangle + (-1)^{n-1} A^{-3n+2}, \quad (4)$$

where

$$\langle K_1 \rangle = -A^3. \quad (5)$$

**Total Angular Defect**

see DESCARTES TOTAL ANGULAR DEFECT

**Total Curvature**

The total curvature of a curve is the quantity  $\sqrt{\tau^2 + \kappa^2}$ , where  $\tau$  is the TORSION and  $\kappa$  is the CURVATURE. The total curvature is also called the THIRD CURVATURE.  
 see also CURVATURE, TORSION (DIFFERENTIAL GEOMETRY)

**Total Differential**

see EXACT DIFFERENTIAL

**Total Function**

A FUNCTION defined for all possible input values.

**Total Intersection Theorem**

If one part of the total intersection group of a curve of order  $n$  with a curve of order  $n_1 + n_2$  constitutes the total intersection with a curve of order  $n_1$ , then the other part will constitute the total intersection with a curve of order  $n_2$ .

**References**

- Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 32, 1959.

**Total Order**

A total order satisfies the conditions for a PARTIAL ORDER plus the comparability condition. A RELATION  $\leq$  is a partial order on a SET  $S$  if

1. Reflexivity:  $a \leq a$  for all  $a \in S$
2. Antisymmetry:  $a \leq b$  and  $b \leq a$  implies  $a = b$
3. Transitivity:  $a \leq b$  and  $b \leq c$  implies  $a \leq c$ ,

and is a total order if, in addition,

4. Comparability: For any  $a, b \in S$ , either  $a \leq b$  or  $b \leq a$ .

see also PARTIAL ORDER, RELATION

**Total Space**

The SPACE  $E$  of a FIBER BUNDLE given by the MAP  $f: E \rightarrow B$ , where  $B$  is the BASE SPACE of the FIBER BUNDLE.

see also BASE SPACE, FIBER BUNDLE, SPACE

**Totative**

A POSITIVE INTEGER less than or equal to a number  $n$  which is also RELATIVELY PRIME to  $n$ , where 1 is counted as being RELATIVELY PRIME to all numbers. The number of totatives of  $n$  is the value of the TOTIENT FUNCTION  $\phi(n)$ .

see also RELATIVELY PRIME, TOTIENT FUNCTION

**Totient Function**

The totient function  $\phi(n)$ , also called Euler's totient function, is defined as the number of POSITIVE INTEGERS  $\leq n$  which are RELATIVELY PRIME to (i.e., do not contain any factor in common with)  $n$ , where 1 is counted as being RELATIVELY PRIME to all numbers. Since a number less than or equal to and RELATIVELY PRIME to a given number is called a TOTATIVE, the totient function  $\phi(n)$  can be simply defined as the number of TOTATIVES of  $n$ . For example, there are eight TOTATIVES of 24 (1, 5, 7, 11, 13, 17, 19, and 23), so  $\phi(24) = 8$ .

By convention,  $\phi(0) = 1$ . The first few values of  $\phi(n)$  for  $n = 1, 2, \dots$  are 1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, ... (Sloane's A000010).  $\phi(n)$  is plotted above for small  $n$ .

For a PRIME  $p$ ,

$$\phi(p) = p - 1, \quad (1)$$

since all numbers less than  $p$  are RELATIVELY PRIME to  $p$ . If  $m = p^\alpha$  is a POWER of a PRIME, then the numbers which have a common factor with  $m$  are the multiples of  $p$ :  $p, 2p, \dots, (p^{\alpha-1})p$ . There are  $p^{\alpha-1}$  of these multiples, so the number of factors RELATIVELY PRIME to  $p^\alpha$  is

$$\phi(p^\alpha) = p^\alpha - p^{\alpha-1} = p^{\alpha-1}(p - 1) = p^\alpha \left(1 - \frac{1}{p}\right). \quad (2)$$

Now take a general  $m$  divisible by  $p$ . Let  $\phi_p(m)$  be the number of POSITIVE INTEGERS  $\leq m$  not DIVISIBLE by  $p$ . As before,  $p, 2p, \dots, (m/p)p$  have common factors, so

$$\phi_p(m) = m - \frac{m}{p} = m \left(1 - \frac{1}{p}\right). \quad (3)$$

Now let  $q$  be some other PRIME dividing  $m$ . The INTEGERS divisible by  $q$  are  $q, 2q, \dots, (m/q)q$ . But these duplicate  $pq, 2pq, \dots, (m/pq)pq$ . So the number of terms which must be subtracted from  $\phi_p$  to obtain  $\phi_{pq}$  is

$$\Delta\phi_q(m) = \frac{m}{q} - \frac{m}{pq} = \frac{m}{q} \left(1 - \frac{1}{p}\right), \quad (4)$$

and

$$\begin{aligned} \phi_{pq}(m) &\equiv \phi_q(m) - \Delta\phi_q(m) \\ &= m \left(1 - \frac{1}{p}\right) - \frac{m}{q} \left(1 - \frac{1}{p}\right) \\ &= m \left(1 - \frac{1}{p}\right) \left(1 - \frac{1}{q}\right). \end{aligned} \quad (5)$$

By induction, the general case is then

$$\phi(n) = n \left(1 - \frac{1}{p_1}\right) \left(1 - \frac{1}{p_2}\right) \dots \left(1 - \frac{1}{p_r}\right). \quad (6)$$

An interesting identity relates  $\phi(n^2)$  to  $\phi(n)$ ,

$$\phi(n^2) = n\phi(n). \quad (7)$$

Another identity relates the DIVISORS  $d$  of  $n$  to  $n$  via

$$\sum_d \phi(d) = n. \quad (8)$$

The DIVISOR FUNCTION satisfies the CONGRUENCE

$$n\sigma(n) \equiv 2 \pmod{\phi(n)} \quad (9)$$

for all PRIMES and no COMPOSITE with the exceptions of 4, 6, and 22 (Subbarao 1974), where  $\sigma(n)$  is the DIVISOR FUNCTION. No COMPOSITE solution is currently known to

$$n - 1 \equiv 0 \pmod{\phi(n)} \quad (10)$$

(Honsberger 1976, p. 35).

Walfisz (1963), building on the work of others, showed that

$$\sum_{n=1}^N \phi(n) = \frac{3N^2}{\pi^2} + \mathcal{O}[N(\ln N)^{2/3}(\ln \ln N)^{4/3}], \quad (11)$$

and Landau (1900, quoted in Dickson 1952) showed that

$$\sum_{n=1}^N \frac{1}{\phi(n)} = A \ln N + B + \mathcal{O}\left(\frac{\ln N}{N}\right), \quad (12)$$

where

$$\begin{aligned} A &= \sum_{k=1}^{\infty} \frac{[\mu(k)]^2}{k\phi(k)} = \frac{\zeta(2)\zeta(3)}{\zeta(6)} = \frac{315}{2\pi^4}\zeta(3) \\ &= 1.9435964368\dots \end{aligned} \quad (13)$$

$$\begin{aligned} B &= \gamma \frac{315}{2\pi^4}\zeta(3) - \sum_{k=1}^{\infty} \frac{[\mu(k)]^2 \ln k}{k\phi(k)} \\ &= -0.0595536246\dots, \end{aligned} \quad (14)$$

$\mu(k)$  is the MÖBIUS FUNCTION,  $\zeta(z)$  is the RIEMANN ZETA FUNCTION, and  $\gamma$  is the EULER-MASCHERONI CONSTANT (Dickson).  $A$  can also be written

$$A = \prod_{k=1}^{\infty} \frac{1 - p_k^{-6}}{(1 - p_k^{-2})(1 - p_k^{-3})} = \prod_{k=1}^{\infty} \left[ 1 + \frac{1}{p_k(p_k - 1)} \right]. \quad (15)$$

Note that this constant is similar to ARTIN'S CONSTANT.

If the GOLDBACH CONJECTURE is true, then for every number  $m$ , there are PRIMES  $p$  and  $q$  such that

$$\phi(p) + \phi(q) = 2m \quad (16)$$

(Guy 1994, p. 105).

Curious equalities of consecutive values include

$$\phi(5186) = \phi(5187) = \phi(5188) = 2^5 3^4 \quad (17)$$

$$\phi(25930) = \phi(25935) = \phi(25940) = \phi(25942) = 2^7 3^4 \quad (18)$$

$$\phi(404471) = \phi(404473) = \phi(404477) = 2^8 3^2 5^2 7 \quad (19)$$

(Guy 1994, p. 91).

The SUMMATORY totient function, plotted above, is defined by

$$\Phi(n) \equiv \sum_{k=1}^n \phi(k) \quad (20)$$

and has the asymptotic series

$$\Phi(x) \sim \frac{1}{2\zeta(2)} x^2 + (x \ln x) \quad (21)$$

$$\sim \frac{3}{\pi^2} x^2 + \mathcal{O}(x \ln x), \quad (22)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION (Perrot 1881). The first values of  $\Phi(n)$  are 1, 2, 4, 6, 10, 12, 18, 22, 28, ... (Sloane's A002088).

## Totient Function Constants

see SILVERMAN CONSTANT, TOTIENT FUNCTION

## Totient Valence Function

$N_\phi(m)$  is the number of INTEGERS  $n$  for which  $\phi(n) = m$ , also called the MULTIPLICITY of  $m$  (Guy 1994). The table below lists values for  $\phi(N) \leq 50$ .

$\phi(N)$	$m$	$N$
1	2	1, 2
2	3	3, 4, 6
4	4	5, 8, 10, 12
6	4	7, 9, 14, 18
8	5	15, 16, 20, 24, 30
10	2	11, 22
12	6	13, 21, 26, 28, 36, 42
16	6	17, 32, 34, 40, 48, 60
18	4	19, 27, 38, 54
20	5	25, 33, 44, 50, 66
22	2	23, 46
24	10	35, 39, 45, 52, 56, 70, 72, 78, 84, 90
28	2	29, 58
30	2	31, 62
32	7	51, 64, 68, 80, 96, 102, 120
36	8	37, 57, 63, 74, 76, 108, 114, 126
40	9	41, 55, 75, 82, 88, 100, 110, 132, 150
42	4	43, 49, 86, 98
44	3	69, 92, 138
46	2	47, 94
48	11	65, 104, 105, 112, 130, 140, 144, 156, 168, 180, 210

A table listing the first value of  $\phi(N)$  with multiplicities up to 100 follows (Sloane's A014573).

$M$	$\phi$	$M$	$\phi$	$M$	$\phi$	$M$	$\phi$
0	3	26	2560	51	4992	76	21840
2	1	27	384	52	17640	77	9072
3	2	28	288	53	2016	78	38640
4	4	29	1320	54	1152	79	9360
5	8	30	3696	55	6000	80	81216
6	12	31	240	56	12288	81	4032
7	32	32	768	57	4752	82	5280
8	36	33	9000	58	2688	83	4800
9	40	34	432	59	3024	84	4608
10	24	35	7128	60	13680	85	16896
11	48	36	4200	61	9984	86	3456
12	160	37	480	62	1728	87	3840
13	396	38	576	63	1920	88	10800
14	2268	39	1296	64	2400	89	9504
15	704	40	1200	65	7560	90	18000
16	312	41	15936	66	2304	91	23520
17	72	42	3312	67	22848	92	39936
18	336	43	3072	68	8400	93	5040
19	216	44	3240	69	29160	94	26208
20	936	45	864	70	5376	95	27360
21	144	46	3120	71	3360	96	6480
22	624	47	7344	72	1440	97	9216
23	1056	48	3888	73	13248	98	2880
24	1760	49	720	74	11040	99	26496
25	360	50	1680	75	27720	100	34272

It is thought that  $N_\phi(m) \geq 2$  (i.e., the totient valence function never takes on the value 1), but this has not been proven. This assertion is called CARMICHAEL'S TOTIENT FUNCTION CONJECTURE and is equivalent to the statement that for all  $n$ , there exists  $m \neq n$  such that  $\phi(n) = \phi(m)$  (Ribenoim 1996, pp. 39–40). Any counterexample must have more than 10,000,000 DIGITS (Schlafly and Wagon 1994, Conway and Guy 1996).

#### Tournament Matrix

A matrix for a round-robin tournament involving  $n$  players competing in  $n(n-1)/2$  matches (no ties allowed) having entries

$$a_{ij} = \begin{cases} 1 & \text{if player } i \text{ defeats player } j \\ -1 & \text{if player } i \text{ loses to player } j \\ 0 & \text{if } i = j. \end{cases}$$

The MATRIX satisfies

$$A + A^T + I = J,$$

where  $I$  is the IDENTITY MATRIX,  $J$  is an  $n \times n$  MATRIX of all 1s, and  $A^T$  is the MATRIX TRANSPOSE of  $A$ .

The tournament matrix for  $n$  players has zero DETERMINANT IFF  $n$  is ODD (McCarthy and Benjamin 1996). The dimension of the NULLSPACE of an  $n$ -player tournament matrix is

$$\dim[\text{nullspace}] = \begin{cases} 0 & \text{for } n \text{ even} \\ 1 & \text{for } n \text{ odd} \end{cases}$$

(McCarthy 1996).

### Tower of Power

see POWER TOWER

### Towers of Hanoi

A PUZZLE invented by E. Lucas in 1883. Given a stack of  $n$  disks arranged from largest on the bottom to smallest on top placed on a rod, together with two empty rods, the towers of Hanoi puzzle asks for the minimum number of moves required to reverse the order of the stack (where moves are allowed only if they place smaller disks on top of larger disks). The problem is ISOMORPHIC to finding a HAMILTONIAN PATH on an  $n$ -HYPERCUBE.

For  $n$  disks, the number of moves  $h_n$  required is given by the RECURRENCE RELATION

$$h_n = 2h_{n-1} + 1.$$

Solving gives

$$h_n = 2^n - 1.$$

The number of disks moved after the  $k$ th step is the same as the element which needs to be added or deleted in the  $k$ th ADDEND of the RYSER FORMULA (Gardner 1988, Vardi 1991).

A HANOI GRAPH can be constructed whose VERTICES correspond to legal configurations of  $n$  towers of Hanoi, where the VERTICES are adjacent if the corresponding configurations can be obtained by a legal move. It can be solved using a binary GRAY CODE.

Poole (1994) gives *Mathematica*® (Wolfram Research, Champaign, IL) routines for solving an arbitrary disk configuration in the fewest possible moves. The proof of minimality is achieved using the LUCAS CORRESPONDENCE which relates PASCAL'S TRIANGLE to the HANOI GRAPH. ALGORITHMS are known for transferring disks for four pegs, but none has been proved minimal. For additional references, see Poole (1994).

### Trace (Complex)

The image of the path  $\gamma$  in  $\mathbb{C}$  under the FUNCTION  $f$  is called the trace. This term is unrelated to that applied to MATRICES and TENSORS.

### Trace (Group)

see CHARACTER (GROUP)

### Trace (Map)

Let a PATCH be given by the map  $\mathbf{x} : U \rightarrow \mathbb{R}^n$ , where  $U$  is an open subset of  $\mathbb{R}^2$ , or more generally by  $\mathbf{x} : A \rightarrow \mathbb{R}^n$ , where  $A$  is any SUBSET of  $\mathbb{R}^2$ . Then  $\mathbf{x}(U)$  (or more generally,  $\mathbf{x}(A)$ ) is called the trace of  $\mathbf{x}$ .

see also PATCH

### Trace (Matrix)

The trace of an  $n \times n$  SQUARE MATRIX  $A$  is defined by

$$\text{Tr}(A) \equiv a_{ii}, \quad (1)$$

where EINSTEIN SUMMATION is used (i.e., the  $a_{ii}$  is summed over  $i = 1, \dots, n$ ). For SQUARE MATRICES  $A$  and  $B$ , it is true that

$$\text{Tr}(A) = \text{Tr}(A^T) \quad (2)$$

$$\text{Tr}(A + B) = \text{Tr}(A) + \text{Tr}(B) \quad (3)$$

$$\text{Tr}(\alpha A) = \alpha \text{Tr}(A) \quad (4)$$

(Lange 1987, p. 40). The trace is invariant under a SIMILARITY TRANSFORMATION

$$A' \equiv BAB^{-1} \quad (5)$$

(Lange 1987, p. 64). Since

$$(bab^{-1})_{ij} = b_{il}a_{lk}b_{kj}^{-1}, \quad (6)$$

$$\begin{aligned} \text{Tr}(BAB^{-1}) &= b_{il}a_{lk}b^{-1}_{ki} \\ &= (b^{-1}b)_{ki}a_{lk} = \delta_{ki}a_{lk} \\ &= a_{kk} = \text{Tr}(A), \end{aligned} \quad (7)$$

where  $\delta_{ij}$  is the KRONECKER DELTA.

The trace of a product of square matrices is independent of the order of the multiplication since

$$\begin{aligned} \text{Tr}(AB) &= (ab)_{ii} = a_{ij}b_{ji} = b_{ji}a_{ij} \\ &= (ba)_{jj} = \text{Tr}(BA). \end{aligned} \quad (8)$$

Therefore, the trace of the COMMUTATOR of  $A$  and  $B$  is given by

$$\text{Tr}([A, B]) \equiv \text{Tr}(AB) - \text{Tr}(BA) = 0. \quad (9)$$

The product of a SYMMETRIC and an ANTISYMMETRIC MATRIX has zero trace,

$$\text{Tr}(A_S B_A) = 0. \quad (10)$$

The value of the trace can be found using the fact that the matrix can always be transformed to a coordinate system where the  $z$ -AXIS lies along the axis of rotation. In the new coordinate system, the MATRIX is

$$A' = \begin{bmatrix} \cos \phi & \sin \phi & 0 \\ -\sin \phi & \cos \phi & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad (11)$$

so the trace is

$$\text{Tr}(A') = \text{Tr}(A) \equiv a_{ii} = 1 + 2 \cos \phi. \quad (12)$$

### References

Lang, S. *Linear Algebra*, 3rd ed. New York: Springer-Verlag, pp. 40 and 64, 1987.

### Trace (Tensor)

The trace of a second-RANK TENSOR  $T$  is a SCALAR given by the CONTRACTED mixed TENSOR equal to  $T_i^i$ . The trace satisfies

$$\text{Tr} \left[ M^{-1}(x) \frac{\partial}{\partial x^\lambda} M(x) \right] = \frac{\partial}{\partial x^\lambda} \ln[\det(x)],$$

and

$$\begin{aligned} \delta \ln[\det M] &= \ln[\det(M + \delta M)] - \ln(\det M) \\ &= \ln \left[ \frac{\det(M + \delta M)}{\det M} \right] \\ &= \ln[\det M^{-1}(M + \delta M)] \\ &= \ln[\det(1 + M^{-1}\delta M)] \\ &\approx \ln[1 + \text{Tr}(M^{-1}\delta M)] \\ &\approx \text{Tr}(M^{-1}\delta M). \end{aligned}$$

see also CONTRACTION (TENSOR)

### Tractory

see TRACTRIX

### Tractrix

The tractrix is the CATENARY INVOLUTE described by a point initially on the vertex. It has a constant NEGATIVE CURVATURE and is sometimes called the TRACTORY or EQUITANGENTIAL CURVE. The tractrix was first studied by Huygens in 1692, who gave it the name "tractrix." Later, Leibniz, Johann Bernoulli, and others studied the curve.

The tractrix arises from the following problem posed to Leibniz: What is the path of an object starting off with a vertical offset when it is dragged along by a string of constant length being pulled along a straight horizontal line? By associating the object with a dog, the string with a leash, and the pull along a horizontal line with the dog's master, the curve has the descriptive name HUNDKURVE (hound curve) in German. Leibniz found the curve using the fact that the axis is an asymptote to the tractrix (MacTutor Archive).

In CARTESIAN COORDINATES the tractrix has equation

$$x = a \operatorname{sech}^{-1} \left( \frac{y}{a} \right) - \sqrt{a^2 - y^2}. \quad (1)$$

One parametric form is

$$x(t) = a(t - \tanh t) \quad (2)$$

$$y(t) = a \operatorname{sech} t. \quad (3)$$

The ARC LENGTH, CURVATURE, and TANGENTIAL ANGLE are

$$s(t) = \ln(\cosh t) \quad (4)$$

$$\kappa(t) = \operatorname{csch} t \quad (5)$$

$$\phi(t) = 2 \tan^{-1}[\tanh(\tfrac{1}{2}t)]. \quad (6)$$

A second parametric form in terms of the ANGLE  $\phi$  of the straight line tangent to the tractrix is

$$x = a\{\ln[\tan(\tfrac{1}{2}\phi)] + \cos \phi\} \quad (7)$$

$$y = a \sin \phi \quad (8)$$

(Gray 1993). This parameterization has CURVATURE

$$\kappa(\phi) = |\tan \phi|. \quad (9)$$

A parameterization which traverses the tractrix with constant speed  $a$  is given by

$$x(t) = \begin{cases} ae^{-v/a} & \text{for } v \in [0, \infty) \\ ae^{v/a} & \text{for } v \in (-\infty, 0] \end{cases} \quad (10)$$

$$y(t) = \begin{cases} a[\tanh^{-1}(\sqrt{1 - e^{-2v/a}}) - \sqrt{1 - e^{-2v/a}}] & \text{for } v \in [0, \infty) \\ a[-\tanh^{-1}(\sqrt{1 - e^{2v/a}}) + \sqrt{1 - e^{2v/a}}] & \text{for } v \in (-\infty, 0]. \end{cases} \quad (11)$$

When a tractrix is rotated around its asymptote, a PSEUDOSPHERE results. This is a surface of constant NEGATIVE CURVATURE. For a tractrix, the length of a TANGENT from its point of contact to an asymptote is constant. The AREA between the tractrix and its asymptote is finite.

see also CURVATURE, DINI'S SURFACE, MICE PROBLEM, PSEUDOSPHERE, PURSUIT CURVE, TRACTROID

Yates, R. C. "Tractrix." *A Handbook on Curves and Their Properties*. Ann Arbor, MI: J. W. Edwards, pp. 221–224, 1952.

#### Tractrix Evolute

The EVOLUTE of the TRACTRIX is the CATENARY.

#### Tractrix Radial Curve

The RADIAL CURVE of the TRACTRIX is the KAPPA CURVE.

#### Tractroid

The SURFACE OF REVOLUTION produced by revolving the TRACTRIX

$$x = \operatorname{sech} u \quad (1)$$

$$z = u - \tanh u \quad (2)$$

about the  $z$ -AXIS is a tractroid given by

$$x = \operatorname{sech} u \cos v \quad (3)$$

$$y = \operatorname{sech} u \sin v \quad (4)$$

$$z = u - \tanh u. \quad (5)$$

see also PSEUDOSPHERE, SURFACE OF REVOLUTION, TRACTRIX

#### Transcendental Curve

A curve which intersects some straight line in an infinity of points (but for which not every point lies on this curve).

#### References

- Borwein, J. M.; Borwein, P. B.; and Bailey, D. H. "Ramanujan, Modular Equations, and Approximations to Pi or How to Compute One Billion Digits of Pi." *Amer. Math. Monthly* **96**, 201–219, 1989.

#### Transcendental Equation

An equation or formula involving TRANSCENDENTAL FUNCTIONS.

**Transcendental Function**

A function which “transcends,” i.e., cannot be expressed in terms of, the usual ELEMENTARY FUNCTIONS. Define

$$\begin{aligned} l_1(z) &\equiv l(z) \equiv \ln(z) \\ e_1(z) &\equiv e(z) \equiv e^z \\ \varsigma_1 f(z) &\equiv \varsigma f(z) \equiv \int f(z) dz, \end{aligned}$$

and let  $l_2 \equiv l(l(z))$ , etc. These are called the “elementary” transcendental functions (Watson 1966, p. 111).

see also ALGEBRAIC FUNCTION, ELEMENTARY FUNCTION

**References**

Watson, G. N. *A Treatise on the Theory of Bessel Functions*, 2nd ed. Cambridge, England: Cambridge University Press, 1966.

**Transcendental Number**

A number which is not the ROOT of any POLYNOMIAL equation with INTEGER COEFFICIENTS, meaning that it not an ALGEBRAIC NUMBER of any degree, is said to be transcendental. This definition guarantees that every transcendental number must also be IRRATIONAL, since a RATIONAL NUMBER is, by definition, an ALGEBRAIC NUMBER of degree one.

Transcendental numbers are important in the history of mathematics because their investigation provided the first proof that CIRCLE SQUARING, one of the GEOMETRIC PROBLEMS OF ANTIQUITY which had baffled mathematicians for more than 2000 years was, in fact, insoluble. Specifically, in order for a number to be produced by a GEOMETRIC CONSTRUCTION using the ancient Greek rules, it must be either RATIONAL or a very special kind of ALGEBRAIC NUMBER known as a EUCLIDEAN NUMBER. Because the number  $\pi$  is transcendental, the construction cannot be done according to the Greek rules.

Georg Cantor was the first to prove the EXISTENCE of transcendental numbers. Liouville subsequently showed how to construct special cases (such as LIOUVILLE'S CONSTANT) using LIOUVILLE'S RATIONAL APPROXIMATION THEOREM. In particular, he showed that any number which has a rapidly converging sequence of rational approximations must be transcendental. For many years, it was only known how to determine if special classes of numbers were transcendental. The determination of the status of more general numbers was considered an important enough unsolved problem that it was one of HILBERT'S PROBLEMS.

Great progress was subsequently made by GELFOND'S THEOREM, which gives a general rule for determining if special cases of numbers of the form  $\alpha^\beta$  are transcendental. Baker produced a further revolution by proving the transcendence of sums of numbers of the form  $\alpha \ln \beta$  for ALGEBRAIC NUMBERS  $\alpha$  and  $\beta$ .

The number  $e$  was proven to be transcendental by Hermite in 1873, and  $\pi$  ( $\pi$ ) by Lindemann in 1882.  $e^\pi$  is transcendental by GELFOND'S THEOREM since

$$(-1)^{-i} = (e^{i\pi})^{-i} = e^\pi.$$

The GELFOND-SCHNEIDER CONSTANT  $2^{\sqrt{2}}$  is also transcendental. Other known transcendentals are  $\sin 1$  where  $\sin x$  is the SINE function,  $J_0(1)$  where  $J_0(x)$  is a BESSEL FUNCTION OF THE FIRST KIND (Hardy and Wright 1985),  $\ln 2$ ,  $\ln 3 / \ln 2$ , the first zero  $x_0 = 2.4048255 \dots$  of the BESSEL FUNCTION  $J_0(x_0)$  (Le Lionnais 1983, p. 46),  $\pi + \ln 2 + \sqrt{2} \ln 3$  (Borwein *et al.* 1989), the THUE-MORSE CONSTANT  $P = 0.4124540336 \dots$  (Dekking 1977, Allouche and Shallit), the CHAMPERNOWNE CONSTANT  $0.1234567891011 \dots$ , the THUE CONSTANT

$$0.110110111110110111110110110 \dots,$$

$\Gamma(\frac{1}{3})$  (Le Lionnais 1983, p. 46),  $\Gamma(\frac{1}{4})\pi^{-1/4}$  (Davis 1959), and  $\Gamma(\frac{1}{4})$  (Chudnovsky, Waldschmidt), where  $\Gamma(x)$  is the GAMMA FUNCTION. At least one of  $\pi e$  and  $\pi + e$  (and probably both) are transcendental, but transcendence has not been proven for either number on its own.

It is not known if  $e^e$ ,  $\pi^\pi$ ,  $\pi^e$ ,  $\gamma$  (the EULER-MASCHERONI CONSTANT),  $I_0(2)$ , or  $I_1(2)$  (where  $I_n(x)$  is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND) are transcendental.

The “degree” of transcendence of a number can be characterized by a so-called LIOUVILLE-ROTH CONSTANT. There are still many fundamental and outstanding problems in transcendental number theory, including the CONSTANT PROBLEM and SCHANUEL'S CONJECTURE.

see also ALGEBRAIC NUMBER, CONSTANT PROBLEM, GELFOND'S THEOREM, IRRATIONAL NUMBER, LINDEMANN-WEIERSTRASS THEOREM, LIOUVILLE-ROTH CONSTANT, ROTH'S THEOREM, SCHANUEL'S CONJECTURE, THUE-SIEGEL-ROTH THEOREM

## Transcritical Bifurcation

Let  $f : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$  be a one-parameter family of  $C^2$  maps satisfying

$$f(0, \mu) = 0 \quad (1)$$

$$\left[ \frac{\partial f}{\partial x} \right]_{\mu=0, x=0} = 1 \quad (2)$$

$$\left[ \frac{\partial f}{\partial x} \right]_{\mu, x} = \left[ \frac{\partial f}{\partial x} \right]_{\mu=0, x=\mu} \quad (3)$$

$$\left[ \frac{\partial^2 f}{\partial x \partial \mu} \right]_{0,0} > 0 \quad (4)$$

$$\left[ \frac{\partial^2 f}{\partial \mu^2} \right]_{\mu=0, x=0} > 0. \quad (5)$$

Then there are two branches, one stable and one unstable. This BIFURCATION is called a transcritical bifurcation. An example of an equation displaying a transcritical bifurcation is

$$\dot{x} = \mu x - x^2. \quad (6)$$

(Guckenheimer and Holmes 1997, p. 145).

see also BIFURCATION

## Transfer Function

The engineering terminology for one use of FOURIER TRANSFORMS. By breaking up a wave pulse into its frequency spectrum

$$f_\nu = F(\nu)e^{2\pi i\nu t}, \quad (1)$$

the entire signal can be written as a sum of contributions from each frequency,

$$f(t) = \int_{-\infty}^{\infty} f_\nu d\nu = \int_{-\infty}^{\infty} F(\nu)e^{2\pi i\nu t} d\nu. \quad (2)$$

If the signal is modified in some way, it will become

$$g_\nu(t) = \phi(\nu)f_\nu(t) = \phi(\nu)F(\nu)e^{2\pi i\nu t} \quad (3)$$

$$g(t) = \int_{-\infty}^{\infty} g_\nu(t) dt = \int_{-\infty}^{\infty} \phi(\nu)F(\nu)e^{2\pi i\nu t} d\nu, \quad (4)$$

where  $\phi(\nu)$  is known as the "transfer function." FOURIER TRANSFORMING  $\phi$  and  $F$ ,

$$\phi(\nu) = \int_{-\infty}^{\infty} \Phi(t)e^{-2\pi i\nu t} dt \quad (5)$$

$$F(\nu) = \int_{-\infty}^{\infty} f(t)e^{-2\pi i\nu t} dt. \quad (6)$$

From the CONVOLUTION THEOREM,

$$g(t) = f(t) * \Phi(t) = \int_{-\infty}^{\infty} f(t)\Phi(t - \tau) d\tau. \quad (7)$$

see also CONVOLUTION THEOREM, FOURIER TRANSFORM

## Transfinite Diameter

Let

$$\phi(z) = cz + c_0 + c_1z^{-1} + c_2z^{-2} + \dots$$

be an ANALYTIC FUNCTION, REGULAR and UNIVALENT for  $|z| > 1$ , which maps  $|z| > 1$  CONFORMALLY onto the region  $T$  preserving the POINT AT INFINITY and its direction. Then the function  $\phi(z)$  is uniquely determined and  $c$  is called the transfinite diameter, sometimes also known as ROBIN'S CONSTANT or the CAPACITY of  $\phi(z)$ .

see also ANALYTIC FUNCTION, REGULAR FUNCTION, UNIVALENT FUNCTION

## Transfinite Number

One of Cantor's ORDINAL NUMBERS  $\omega, \omega + 1, \omega + 2, \dots, \omega + \omega, \omega + \omega + 1, \dots$  which is "larger" than any WHOLE NUMBER.

see also  $\aleph_0, \aleph_1$ , CARDINAL NUMBER, CONTINUUM, ORDINAL NUMBER, WHOLE NUMBER

## References

- Pappas, T. "Transfinite Numbers." *The Joy of Mathematics*. San Carlos, CA: Wide World Publ./Tetra, pp. 156–158, 1989.

## Transform

A shortened term for INTEGRAL TRANSFORM.

Geometrically, if  $S$  and  $T$  are two transformations, then the SIMILARITY TRANSFORMATION  $TST^{-1}$  is sometimes called the transform (Woods 1961).

see also ABEL TRANSFORM, BOUSTROPHEDON TRANSFORM, DISCRETE FOURIER TRANSFORM, FAST FOURIER TRANSFORM, FOURIER TRANSFORM, FRACTIONAL FOURIER TRANSFORM, HANKEL TRANSFORM, HARTLEY TRANSFORM, HILBERT TRANSFORM, LAPLACE-STIELTJES TRANSFORM, LAPLACE TRANSFORM, MELLIN TRANSFORM, NUMBER THEORETIC TRANSFORM, PONCELET TRANSFORM, RADON TRANSFORM, WAVELET TRANSFORM,  $z$ -TRANSFORM,  $Z$ -TRANSFORM

#### References

Woods, F. S. *Higher Geometry: An Introduction to Advanced Methods in Analytic Geometry*. New York: Dover, p. 5, 1961.

### Transformation

see FUNCTION, MAP

#### Transitive

A RELATION  $R$  on a SET  $S$  is transitive provided that for all  $x, y$  and  $z$  in  $S$  such that  $xRy$  and  $yRz$ , we also have  $xRz$ .

see also ASSOCIATIVE, COMMUTATIVE, RELATION

#### Transitive Closure

The transitive closure of a binary RELATION  $R$  on a SET  $X$  is the minimal TRANSITIVE relation  $R'$  on  $X$  that contains  $R$ . Thus  $aR'b$  for any elements  $a$  and  $b$  of  $X$ , provided either that  $aRb$  or that there exists some element  $c$  of  $X$  such that  $aRc$  and  $cRb$ .

see also REFLEXIVE CLOSURE, TRANSITIVE REDUCTION

#### Transitive Reduction

The transitive reduction of a binary RELATION  $R$  on a SET  $X$  is the minimum relation  $R'$  on  $X$  with the same TRANSITIVE CLOSURE as  $R$ . Thus  $aR'b$  for any elements  $a$  and  $b$  of  $X$ , provided that  $aRb$  and there exists no element  $c$  of  $X$  such that  $aRc$  and  $cRb$ .

see also REFLEXIVE REDUCTION, TRANSITIVE CLOSURE

#### Transitivity Class

Let  $S(T)$  be the group of symmetries which map a MONOHEDRAL TILING  $T$  onto itself. The TRANSITIVITY CLASS of a given tile  $T$  is then the collection of all tiles to which  $T$  can be mapped by one of the symmetries of  $S(T)$ .

see also MONOHEDRAL TILING

#### References

Berglund, J. "Is There a  $k$ -Anisohedral Tile for  $k \geq 5$ ?" *Amer. Math. Monthly* **100**, 585–588, 1993.

### Translation

A transformation consisting of a constant offset with no ROTATION or distortion. In  $n$ -D EUCLIDEAN SPACE, a translation may be specified simply as a VECTOR giving the offset in each of the  $n$  coordinates.

see also AFFINE GROUP, DILATION, EUCLIDEAN GROUP, EXPANSION, GLIDE, IMPROPER ROTATION, INVERSION OPERATION, MIRROR IMAGE, REFLECTION, ROTATION

#### References

Beyer, W. H. (Ed.) *CRC Standard Mathematical Tables*, 28th ed. Boca Raton, FL: CRC Press, p. 211, 1987.

### Translation Relation

A mathematical relationship transforming a function  $f(x)$  to the form  $f(x + a)$ .

see also ARGUMENT ADDITION RELATION, ARGUMENT MULTIPLICATION RELATION, RECURRENCE RELATION, REFLECTION RELATION

### Transpose

The object obtained by replacing all elements  $a_{ij}$  with  $a_{ji}$ . For a second-RANK TENSOR  $a_{ij}$ , the tensor transpose is simply  $a_{ji}$ . The matrix transpose, written  $A^T$ , is the MATRIX obtained by exchanging  $A$ 's rows and columns, and satisfies the identity

$$(A^T)^{-1} = (A^{-1})^T.$$

The product of two transposes satisfies

$$\begin{aligned} (B^T A^T)_{ij} &= (b^T)_{ik} (a^T)_{kj} = b_{ki} a_{jk} = a_{jk} b_{ki} = (AB)_{ji} \\ &= (AB)^T_{ij}. \end{aligned}$$

Therefore,

$$(AB)^T = B^T A^T.$$

### Transpose Map

see PULLBACK MAP

### Transposition

An exchange of two elements of a SET with all others staying the same. A transposition is therefore a PERMUTATION of two elements. For example, the swapping of 2 and 5 to take the list 123456 to 153426 is a transposition.

see also PERMUTATION, TRANSPOSITION ORDER

### Transposition Group

A PERMUTATION GROUP in which the PERMUTATIONS are limited to TRANSPOSITIONS.

see also PERMUTATION GROUP

### Transposition Order

An ordering of PERMUTATIONS in which each two adjacent permutations differ by the TRANSPOSITION of two elements. For the permutations of  $\{1, 2, 3\}$  there are two listings which are in transposition order. One is 123, 132, 312, 321, 231, 213, and the other is 123, 321, 312, 213, 231, 132.

see also LEXICOGRAPHIC ORDER, PERMUTATION

#### References

Ruskey, F. "Information on Combinations of a Set."  
<http://sue.csc.uvic.ca/~cos/inf/comb/CombinationsInfo.html>.

### Transversal Array

A set of  $n$  cells in an  $n \times n$  SQUARE such that no two come from the same row and no two come from the same column. The number of transversals of an  $n \times n$  SQUARE is  $n!$  ( $n$  FACTORIAL).

### Transversal Design

A transversal design  $TD_\lambda(k, n)$  of order  $n$ , block size  $k$ , and index  $\lambda$  is a triple  $(V, G, B)$  such that

1.  $V$  is a set of  $kn$  elements,
2.  $G$  is a partition of  $V$  into  $k$  classes, each of size  $n$  (the "groups"),
3.  $B$  is a collection of  $k$ -subsets of  $V$  (the "blocks"), and
4. Every unordered pair of elements from  $V$  is contained in either exactly one group or in exactly  $\lambda$  blocks, but not both.

#### References

### Transversal Line

A transversal line is a LINE which intersects each of a given set of other lines. It is also called a SEMISECANT.

see also LINE

### Transylvania Lottery

A lottery in which three numbers are picked at random from the INTEGERS 1–14.

see also FANO PLANE

### Trapdoor Function

An easily computed function whose inverse is extremely difficult to compute. An example is the multiplication of two large PRIMES. Finding and verifying two large PRIMES is easy, as is their multiplication. But factorization of the resultant product is very difficult.

see also RSA ENCRYPTION

#### References

Gardner, M. Chs. 13–14 in *Penrose Tiles and Trapdoor Ciphers... and the Return of Dr. Matrix*, reissue ed. New York: W. H. Freeman, pp. 299–300, 1989.

### Trapezium

There are two common definitions of the trapezium. The American definition is a QUADRILATERAL with no PARALLEL sides. The British definition for a trapezium is a QUADRILATERAL with two sides PARALLEL. Such a trapezium is equivalent to a TRAPEZOID and therefore has AREA

$$A = \frac{1}{2}(a + b)h.$$

see also DIAMOND, LOZENGE, PARALLELOGRAM, QUADRILATERAL, RHOMBOID, RHOMBUS, SKEW QUADRILATERAL, TRAPEZOID

### Trapezohedron

The trapezohedra are the DUAL POLYHEDRA of the Archimedean ANTIPRISMS. However, their faces are not TRAPEZOIDS.

see also ANTIPRISM, DIPYRAMID, HEXAGONAL SCALENOEDRON, PRISM, TRAPEZOID

#### References

Cundy, H. and Rollett, A. *Mathematical Models*, 3rd ed. Stradbroke, England: Tarquin Pub., p. 117, 1989.

### Trapezoid

A QUADRILATERAL with two sides PARALLEL. The trapezoid depicted above satisfies

$$m = \frac{1}{2}(a + b)$$

and has AREA

$$A = \frac{1}{2}(a + b)h = mh.$$

The trapezoid is equivalent to the British definition of TRAPEZIUM.

### Trapezoidal Hexecontahedron

see DELTOIDAL HEXECONTAHEDRON

**Trapezoidal Icositetrahedron**

see DELTOIDAL ICOSITETRAHEDRON

**Trapezoidal Rule**

The 2-point NEWTON-COTES FORMULA

$$\int_{x_1}^{x_2} f(x) dx = \frac{1}{2}h(f_1 + f_2) - \frac{1}{2}h^3 f''(\xi),$$

where  $f_i \equiv f(x_i)$ ,  $h$  is the separation between the points, and  $\xi$  is a point satisfying  $x_1 \leq \xi \leq x_2$ . Picking  $\xi$  to maximize  $f''(\xi)$  gives an upper bound for the error in the trapezoidal approximation to the INTEGRAL.

see also BODE'S RULE, HARDY'S RULE, NEWTON-COTES FORMULAS, SIMPSON'S 3/8 RULE, SIMPSON'S RULE, WEDDLE'S RULE

**Traveling Salesman Constants**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let  $L(n, d)$  be the smallest TOUR length for  $n$  points in a  $d$ -D HYPERCUBE. Then there exists a smallest constant  $\alpha(d)$  such that for all optimal TOURS in the HYPERCUBE,

$$\limsup_{n \rightarrow \infty} \frac{L(n, d)}{n^{(d-1)/d} \sqrt{d}} \leq \alpha(d), \quad (1)$$

and a constant  $\beta(d)$  such that for *almost* all optimal tours in the HYPERCUBE,

$$\lim_{n \rightarrow \infty} \frac{L(n, d)}{n^{(d-1)/d} \sqrt{d}} = \beta(d). \quad (2)$$

These constants satisfy the inequalities

$$\begin{aligned} 0.44194 < \gamma_2 = \frac{5}{16} \sqrt{2} \leq \beta(2) \\ &\leq \delta < 0.6508 < 0.75983 < 3^{-1/4} \leq \alpha(2) \\ &\leq \phi < 0.98398 \end{aligned} \quad (3)$$

$$\begin{aligned} 0.37313 < \gamma_3 \leq \beta(3) \leq 12^{1/6} 6^{-1/2} < 0.61772 < 0.64805 \\ &< 2^{1/6} 3^{-1/2} \leq \alpha(3) \leq 0.90422 \end{aligned} \quad (4)$$

**Traveling Salesman Constants**

$$\begin{aligned} 0.34207 < \gamma_4 \leq \beta(4) \leq 12^{1/8} 6^{-1/2} < 0.55696 \\ &< 0.59460 < 2^{-3/4} \leq \alpha(4) \leq 0.8364 \end{aligned} \quad (5)$$

(Fejes Tóth 1940, Verblunsky 1951, Few 1955, Beardwood *et al.* 1959), where

$$\gamma_d \equiv \frac{\Gamma(3 + \frac{1}{d}) [\Gamma(\frac{1}{2}d + 1)]^{1/d}}{2\sqrt{\pi}(d^{1/2} + d^{-1/2})}, \quad (6)$$

$\Gamma(z)$  is the GAMMA FUNCTION,  $\delta$  is an expression involving STRUVE FUNCTIONS and NEUMANN FUNCTIONS,

$$\phi \equiv \frac{280(3 - \sqrt{3})}{840 - 280\sqrt{3} + 4\sqrt{5} - \sqrt{10}} \quad (7)$$

(Karloff 1989), and

$$\psi \equiv \frac{1}{2} 3^{-2/3} (4 + \ln 3)^{2/3} \quad (8)$$

(Goddyn 1990). In the LIMIT  $d \rightarrow \infty$ ,

$$\begin{aligned} 0.24197 < \lim_{d \rightarrow \infty} \gamma_d = \frac{1}{\sqrt{2\pi e}} \leq \liminf_{d \rightarrow \infty} \beta(d) \\ &\leq \limsup_{d \rightarrow \infty} \beta(d) \leq \lim_{d \rightarrow \infty} 12^{1/(2d)} 6^{-1/2} \\ &= \frac{1}{\sqrt{6}} < 0.40825 \end{aligned} \quad (9)$$

and

$$\begin{aligned} 0.24197 < \frac{1}{\sqrt{2\pi e}} \leq \lim_{d \rightarrow \infty} \alpha(d) \\ &\leq \frac{2(3 - \sqrt{3})\theta}{\sqrt{2\pi e}} < 0.4052, \end{aligned} \quad (10)$$

where

$$\frac{1}{2} \leq \theta = \lim_{d \rightarrow \infty} [\theta(d)]^{1/d} \leq 0.6602, \quad (11)$$

and  $\theta(d)$  is the best SPHERE PACKING density in  $d$ -D space (Goddyn 1990, Moran 1984, Kabatyanskii and Levenshtein 1978). Steele and Snyder (1989) proved that the limit  $\alpha(d)$  exists.

Now consider the constant

$$\kappa \equiv \lim_{n \rightarrow \infty} \frac{L(n, 2)}{\sqrt{n}} = \beta(2)\sqrt{2}, \quad (12)$$

so

$$\frac{5}{8} = \gamma_2 \sqrt{2} \leq \kappa \leq \delta \sqrt{2} < 0.9204. \quad (13)$$

The best current estimate is  $\kappa \approx 0.7124$ .

A certain self-avoiding SPACE-FILLING CURVE is an optimal TOUR through a set of  $n$  points, where  $n$  can be arbitrarily large. It has length

$$\lambda \equiv \lim_{m \rightarrow \infty} \frac{L_m}{\sqrt{n_m}} = \frac{4(1 + 2\sqrt{2})\sqrt{51}}{153} = 0.7147827 \dots, \quad (14)$$

where  $L_m$  is the length of the curve at the  $m$ th iteration and  $n_m$  is the point-set size (Moscato and Norman).

### Traveling Salesman Problem

A problem in GRAPH THEORY requiring the most efficient (i.e., least total distance) TOUR (i.e., closed path) a salesman can take through each of  $n$  cities. No general method of solution is known, and the problem is NP-HARD.

### Trawler Problem

A fast boat is overtaking a slower one when fog suddenly sets in. At this point, the boat being pursued changes course, but not speed. How should the pursuing vessel proceed in order to be sure of catching the other boat?

The amazing answer is that the pursuing boat should continue to the point where the slow boat would be if it had set its course directly for the pursuing boat when the fog set in. If the boat is not there, it should proceed in a SPIRAL whose origin is the point where the slow boat was when the fog set in. The SPIRAL can be constructed in such a way that the two boats will intersect before a complete turn is made.

### Tree

A tree is a mathematical structure which can be viewed as either a GRAPH or as a DATA STRUCTURE. The two views are equivalent, since a tree DATA STRUCTURE contains not only a set of elements, but also connections between elements, giving a tree graph.

A tree graph is a set of straight line segments connected at their ends containing no closed loops (cycles). A tree with  $n$  nodes has  $n - 1$  EDGES. The points of connection are known as FORKS and the segments as BRANCHES. Final segments and the nodes at their ends are called LEAVES. A tree with two BRANCHES at each FORK and with one or two LEAVES at the end of each branch is called a BINARY TREE.

When a special node is designated to turn a tree into a ROOTED TREE, it is called the ROOT (or sometimes "EVE.") In such a tree, each of the nodes which is one EDGE further away from a given EDGE is called a CHILD, and nodes connected to the same node are then called SIBLINGS.

Note that two BRANCHES placed end-to-end are equivalent to a single BRANCH which means, for example, that there is only one tree of order 3. The number  $t(n)$  of nonisomorphic trees of order  $n = 1, 2, \dots$  (where trees

of orders 1, 2, ..., 6 are illustrated above), are 1, 1, 1, 2, 3, 6, 11, 23, 47, 106, 235, ... (Sloane's A000055).

Otter showed that

$$\lim_{n \rightarrow \infty} \frac{t(n)n^{5/2}}{\alpha^n} = \beta, \quad (1)$$

(Otter 1948, Harary and Palmer 1973, Knuth 1969), where the constants  $\alpha$  and  $\beta$  are sometimes called OTTER'S TREE ENUMERATION CONSTANTS. Write the GENERATING FUNCTION for ROOTED TREES as

$$f(z) = \sum_{i=0}^{\infty} f_i z^i, \quad (2)$$

where the COEFFICIENTS are

$$f_{i+1} = \frac{1}{i} \sum_{j=1}^i \left( \sum_{d|j} d f_d \right) f_{i-j+1}, \quad (3)$$

with  $f_0 = 0$  and  $f_1 = 1$ . Then

$$\alpha = 2.955765 \dots \quad (4)$$

is the unique POSITIVE ROOT of

$$f\left(\frac{1}{x}\right) = 1, \quad (5)$$

and

$$\beta = \frac{1}{\sqrt{2\pi}} \left[ 1 + \sum_{k=2}^{\infty} f' \left( \frac{1}{\alpha_k} \right) \frac{1}{\alpha_k} \right]^{3/2} = 0.5349485 \dots \quad (6)$$

#### Tree-Planting Problem

see ORCHARD-PLANTING PROBLEM

#### Tree Searching

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

In database structures, two quantities are generally of interest: the average number of comparisons required to

1. Find an existing random record, and
2. Insert a new random record into a data structure.

Some constants which arise in the theory of digital tree searching are

$$\alpha \equiv \sum_{k=1}^{\infty} \frac{1}{2^k - 1} = 1.6066951524 \dots \quad (1)$$

$$\beta \equiv \sum_{n=1}^{\infty} \frac{1}{(2^n - 1)^2} = 1.1373387363 \dots \quad (2)$$

Erdős (1948) proved that  $\alpha$  is IRRATIONAL. The expected number of comparisons for a successful search is

$$E = \frac{\ln n}{\ln 2} + \frac{\gamma - 1}{\ln 2} - \alpha + \frac{3}{2} + \delta(n) + \mathcal{O}(n^{-1/2}) \quad (3)$$

$$\sim \lg n - 0.716644 \dots + \delta(n), \quad (4)$$

and for an unsuccessful search is

$$E = \frac{\ln n}{\ln 2} + \frac{\gamma}{\ln 2} - \alpha + \frac{1}{2} + \delta(n) + \mathcal{O}(n^{-1/2}) \quad (5)$$

$$\sim \lg n - 0.273948 \dots + \delta(n). \quad (6)$$

Here  $\delta(n)$ ,  $\epsilon(s)$ , and  $\rho(n)$  are small-amplitude periodic functions, and LG is the base 2 LOGARITHM. The VARIANCE for searching is

$$V \sim \frac{1}{12} + \frac{\pi^2}{6(\ln 2)^2} - \alpha - \beta + \epsilon(s) \sim 2.844383 \dots + \epsilon(s) \quad (7)$$

and for inserting is

$$V \sim \frac{1}{12} + \frac{\pi^2}{6(\ln 2)^2} - \alpha - \beta + \epsilon(s) \sim 0.763014 \dots + \epsilon(s). \quad (8)$$

The expected number of pairs of twin vacancies in a digital search tree is

$$\langle A_n \rangle = \left[ \theta + 1 - \frac{1}{Q} \left( \frac{1}{\ln 2} + \alpha^2 - \alpha \right) + \rho(n) \right] n + \mathcal{O}(\sqrt{n}), \quad (9)$$

where

$$Q \equiv \prod_{k=1}^{\infty} \left( 1 - \frac{1}{2^k} \right) = 0.2887880950 \dots \quad (10)$$

$$= \frac{1}{3} - \frac{1}{3 \cdot 7} + \frac{1}{3 \cdot 5 \cdot 15} - \frac{1}{3 \cdot 5 \cdot 15 \cdot 21} + \dots \quad (11)$$

$$= \exp \left[ - \sum_{n=1}^{\infty} \frac{1}{n(2^n - 1)} \right] \quad (12)$$

$$= \sqrt{\frac{2\pi}{\ln 2}} \exp \left( \frac{\ln 2}{24} - \frac{\pi^2}{6 \ln 2} \right) \times \prod_{n=1}^{\infty} \left[ 1 - \exp \left( - \frac{4\pi^2 n}{\ln 2} \right) \right] \quad (13)$$

and

$$\theta = \sum_{k=1}^{\infty} \frac{k 2^{k+1}}{1 \cdot 3 \cdot 7 \cdot 16 \dots (2^k - 1)} \sum_{j=1}^k \frac{1}{2^j - 1} = 7.7431319855 \dots \quad (14)$$

(Flajolet and Sedgewick 1986). The linear COEFFICIENT of  $\langle A_n \rangle$  fluctuates around

$$c = \theta + 1 - \frac{1}{Q} \left( \frac{1}{\ln 2} + \alpha^2 - \alpha \right) = 0.3720486812 \dots, \quad (15)$$

which can also be written

$$c = \frac{1}{\ln 2} \int_0^{\infty} \frac{x}{1+x} \times \frac{dx}{(1+x)(1+\frac{1}{2}x)(1+\frac{1}{4}x)(1+\frac{1}{8}x) \dots} \quad (16)$$

(Flajolet and Richmond 1992).

## Trefoil Curve

The plane curve given by the equation

$$x^4 + x^2 y^2 + y^4 = x(x^2 - y^2).$$

## Trefoil Knot

The knot 03<sub>001</sub>, also called the THREEFOIL KNOT, which is the unique PRIME KNOT of three crossings. It has BRAID WORD  $\sigma_1^3$ . The trefoil and its MIRROR IMAGE are not equivalent. The trefoil has ALEXANDER POLYNOMIAL  $-x^2 + x - 1$  and is a (3, 2)-TORUS KNOT. The BRACKET POLYNOMIAL can be computed as follows.

$$\begin{aligned} \langle L \rangle &= A^3 d^{2-1} + A^2 B d^{1-1} + A^2 B d^{1-1} + A B^2 d^{2-1} \\ &\quad + A^2 B d^{1-1} + A B^2 d^{2-1} + A B^2 d^{2-1} + B^3 d^{3-1} \\ &= A^3 d^1 + 3 A^2 B d^0 + 3 A B^2 d^1 + B^3 d^2. \end{aligned}$$

Plugging in

$$\begin{aligned} B &= A^{-1} \\ d &= -A^2 - A^{-2} \end{aligned}$$

gives

$$\langle L \rangle = A^{-7} - A^{-3} - A^5.$$

The normalized one-variable KAUFFMAN POLYNOMIAL  $X$  is then given by

$$\begin{aligned} X_L &= (-A^3)^{-w(L)} \langle L \rangle = (-A^3)^{-3} (A^{-7} - A^{-3} - A^5) \\ &= A^{-4} + A^{-12} - A^{-16}, \end{aligned}$$

where the WRITHE  $w(L) = 3$ . The JONES POLYNOMIAL is therefore

$$V(t) = L(A = t^{-1/4}) = t + t^3 - t^4 = t(1 + t^2 - t^3).$$

Since  $V(t^{-1}) \neq V(t)$ , we have shown that the mirror images are not equivalent.

**Triangle**

A triangle is a 3-sided POLYGON sometimes (but not very commonly) called the TRIGON. All triangles are convex. An ACUTE TRIANGLE is a triangle whose three angles are all ACUTE. A triangle with all sides equal is called EQUILATERAL. A triangle with two sides equal is called ISOSCELES. A triangle having an OBTUSE ANGLE is called an OBTUSE TRIANGLE. A triangle with a RIGHT ANGLE is called RIGHT. A triangle with all sides a different length is called SCALENE.

The sum of ANGLES in a triangle is  $180^\circ$ . This can be established as follows. Let  $DAE \parallel BC$  ( $DAE$  be PARALLEL to  $BC$ ) in the above diagram, then the angles  $\alpha$  and  $\beta$

satisfy  $\alpha = \angle DAB = \angle ABC$  and  $\beta = \angle EAC = \angle BCE$ , as indicated. Adding  $\gamma$ , it follows that

$$\alpha + \beta + \gamma = 180^\circ, \quad (1)$$

since the sum of angles for the line segment must equal two RIGHT ANGLES. Therefore, the sum of angles in the triangle is also  $180^\circ$ .

Let  $S$  stand for a triangle side and  $A$  for an angle, and let a set of  $S$ s and  $A$ s be concatenated such that adjacent letters correspond to adjacent sides and angles in a triangle. Triangles are uniquely determined by specifying three sides (SSS THEOREM), two angles and a side (AAS THEOREM), or two sides with an adjacent angle (SAS THEOREM). In each of these cases, the unknown three quantities (there are three sides and three angles total) can be uniquely determined. Other combinations of sides and angles do not uniquely determine a triangle: three angles specify a triangle only modulo a scale size (AAA THEOREM), and one angle and two sides not containing it may specify one, two, or no triangles (ASS THEOREM).

Equilateral Triangle

The RULER and COMPASS construction of the triangle can be accomplished as follows. In the above figure, take  $OP_0$  as a RADIUS and draw  $OB \perp OP_0$ . Then bisect  $OB$  and construct  $P_2P_1 \parallel OP_0$ . Extending  $BO$  to locate  $P_3$  then gives the EQUILATERAL TRIANGLE  $\Delta P_1P_2P_3$ .

In Proposition IV.4 of the *Elements*, Euclid showed how to inscribe a CIRCLE (the INCIRCLE) in a given triangle by locating the CENTER as the point of intersection of ANGLE BISECTORS. In Proposition IV.5, he showed how to circumscribe a CIRCLE (the CIRCUMCIRCLE) about a given triangle by locating the CENTER as the point of intersection of the perpendicular bisectors.

If the coordinates of the triangle VERTICES are given by  $(x_i, y_i)$  where  $i = 1, 2, 3$ , then the AREA  $\Delta$  is given by the DETERMINANT

$$\Delta = \frac{1}{2!} \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}. \quad (2)$$

If the coordinates of the triangle VERTICES are given in 3-D by  $(x_i, y_i, z_i)$  where  $i = 1, 2, 3$ , then

$$\Delta = \frac{1}{2} \sqrt{\begin{vmatrix} y_1 & z_1 & 1 \\ y_2 & z_2 & 1 \\ y_3 & z_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} z_1 & x_1 & 1 \\ z_2 & x_2 & 1 \\ z_3 & x_3 & 1 \end{vmatrix}^2 + \begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x_3 & y_3 & 1 \end{vmatrix}^2}. \quad (3)$$

In the above figure, let the CIRCUMCIRCLE passing through a triangle's VERTICES have RADIUS  $r$ , and denote the CENTRAL ANGLES from the first point to the second  $\theta_1$ , and to the third point by  $\theta_2$ . Then the AREA of the triangle is given by

$$\Delta = 2r^2 \left| \sin\left(\frac{1}{2}\theta_1\right) \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_1 - \theta_2)\right] \right|. \quad (4)$$

If a triangle has sides  $a, b, c$ , call the angles opposite these sides  $A, B$ , and  $C$ , respectively. Also define the SEMIPERIMETER  $s$  as HALF the PERIMETER:

$$s \equiv \frac{1}{2}p = \frac{1}{2}(a + b + c). \quad (5)$$

The AREA of a triangle is then given by HERON'S FORMULA

$$\Delta = \sqrt{s(s-a)(s-b)(s-c)}, \quad (6)$$

as well by the FORMULAS

$$\Delta = \frac{1}{4} \sqrt{(a+b+c)(b+c-a)(c+a-b)(a+b-c)} \quad (7)$$

$$= \frac{1}{4} \sqrt{2(a^2b^2 + a^2c^2 + b^2c^2) - (a^4 + b^4 + c^4)} \quad (8)$$

$$= \frac{1}{4} \sqrt{[(a+b)^2 - c^2][c^2 - (a-b)^2]} \quad (9)$$

$$= \frac{1}{4} \sqrt{p(p-2a)(p-2b)(p-2c)}, \quad (10)$$

$$= 2R^2 \sin A \sin B \sin C \quad (11)$$

$$= \frac{abc}{4R} = rs \quad (12)$$

$$= \frac{1}{2}ah_a \quad (13)$$

$$= \frac{1}{2}bc \sin A. \quad (14)$$

In the above formulas,  $h_i$  is the ALTITUDE on side  $i$ ,  $R$  is the CIRCUMRADIUS, and  $r$  is the INRADIUS (Johnson 1929, p. 11). Expressing the side lengths  $a$ ,  $b$ , and  $c$  in terms of the radii  $a'$ ,  $b'$ , and  $c'$  of the mutually tangent circles centered on the TRIANGLE vertices (which define the SODDY CIRCLES),

$$a = b' + c' \quad (15)$$

$$b = a' + c' \quad (16)$$

$$c = a' + b', \quad (17)$$

gives the particularly pretty form

$$\Delta = \sqrt{a'b'c'(a' + b' + c')}. \quad (18)$$

For additional FORMULAS, see Beyer (1987) and Baker (1884), who gives 110 FORMULAS for the AREA of a triangle.

The ANGLES of a triangle satisfy

$$\cot A = \frac{b^2 + c^2 - a^2}{4\Delta} \quad (19)$$

where  $\Delta$  is the AREA (Johnson 1929, p. 11, with missing squared symbol added). This gives the pretty identity

$$\cot A + \cot B + \cot C = \frac{a^2 + b^2 + c^2}{4\Delta}. \quad (20)$$

Let a triangle have ANGLES  $A$ ,  $B$ , and  $C$ . Then

$$\sin A \sin B \sin C \leq kABC, \quad (21)$$

where

$$k = \left( \frac{3\sqrt{3}}{2\pi} \right)^3 \quad (22)$$

(Abi-Khuzam 1974, Le Lionnais 1983). This can be used to prove that

$$8\omega^3 < ABC, \quad (23)$$

where  $\omega$  is the BROCARD ANGLE.

TRIGONOMETRIC FUNCTIONS of half angles can be expressed in terms of the triangle sides:

$$\cos(\tfrac{1}{2}A) = \sqrt{\frac{s(s-a)}{bc}} \quad (24)$$

$$\sin(\tfrac{1}{2}A) = \sqrt{\frac{(s-b)(s-c)}{bc}} \quad (25)$$

$$\tan(\tfrac{1}{2}A) = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}, \quad (26)$$

where  $s$  is the SEMIPERIMETER.

The number of different triangles which have INTEGRAL sides and PERIMETER  $n$  is

$$\begin{aligned} T(n) &= P_3(n) - \sum_{1 \leq j \leq \lfloor n/2 \rfloor} P_2(j) \\ &= \left\lfloor \frac{n^2}{12} \right\rfloor - \left\lfloor \frac{n}{4} \right\rfloor \left\lfloor \frac{n+2}{4} \right\rfloor \\ &= \begin{cases} \left\lfloor \frac{n^2}{48} \right\rfloor & \text{for } n \text{ even} \\ \left\lfloor \frac{(n+3)^2}{48} \right\rfloor & \text{for } n \text{ odd,} \end{cases} \end{aligned} \quad (27)$$

where  $P_2$  and  $P_3$  are PARTITION FUNCTIONS  $P$ ,  $[x]$  is the NINT function, and  $\lfloor x \rfloor$  is the FLOOR FUNCTION (Jordan *et al.* 1979, Andrews 1979, Honsberger 1985). The values of  $T(n)$  for  $n = 1, 2, \dots$  are 0, 0, 1, 0, 1, 1, 2, 1, 3, 2, 4, 3, 5, 4, 7, 5, 8, 7, 10, 8, 12, 10, 14, 12, 16, ... (Sloane's A005044), which is also ALCUIN'S SEQUENCE padded with two initial 0s.  $T(n)$  also satisfies

$$T(2n) = T(2n-3) = P_3(n). \quad (28)$$

It is not known if a triangle with INTEGER sides, MEDIANS, and AREA exists (although there are incorrect PROOFS of the impossibility in the literature). However, R. L. Rathbun, A. Kemnitz, and R. H. Buchholz have shown that there are infinitely many triangles with RATIONAL sides (HERONIAN TRIANGLES) with two RATIONAL MEDIANS (Guy 1994).

In the following paragraph, assume the specified sides and angles are adjacent to each other. Specifying three ANGLES does not uniquely define a triangle, but any two triangles with the same ANGLES are similar (the AAA THEOREM). Specifying two ANGLES  $A$  and  $B$  and a side  $a$  uniquely determines a triangle with AREA

$$\Delta = \frac{a^2 \sin B \sin C}{2 \sin A} = \frac{a^2 \sin B \sin(\pi - A - B)}{2 \sin A} \quad (29)$$

(the AAS THEOREM). Specifying an ANGLE  $A$ , a side  $c$ , and an ANGLE  $B$  uniquely specifies a triangle with AREA

$$\Delta = \frac{c^2}{2(\cot A + \cot B)} \quad (30)$$

(the ASA THEOREM). Given a triangle with two sides,  $a$  the smaller and  $c$  the larger, and one known ANGLE  $A$ , ACUTE and opposite  $a$ , if  $\sin A < a/c$ , there are two possible triangles. If  $\sin A = a/c$ , there is one possible triangle. If  $\sin A > a/c$ , there are no possible triangles. This is the ASS THEOREM. Let  $a$  be the base length and  $h$  be the height. Then

$$\Delta = \tfrac{1}{2}ah = \tfrac{1}{2}ac \sin B \quad (31)$$

(the SAS THEOREM). Finally, if all three sides are specified, a unique triangle is determined with AREA given by HERON'S FORMULA or by

$$\Delta = \frac{abc}{4R}, \quad (32)$$

where  $R$  is the CIRCUMRADIUS. This is the SSS THEOREM.

There are four CIRCLES which are tangent to the sides of a triangle, one internal and the rest external. Their centers are the points of intersection of the ANGLE BISECTORS of the triangle.

Any triangle can be positioned such that its shadow under an orthogonal projection is EQUILATERAL.

## Triangle Arcs

In the above figure, the curves are arcs of a CIRCLE and

$$a = BC \quad (1)$$

$$b = CA = CP \quad (2)$$

$$c = BA = BQ. \quad (3)$$

Then

$$PQ^2 = 2BP \cdot QC. \quad (4)$$

The figure also yields the algebraic identity

$$(b + c - \sqrt{b^2 + c^2})^2 = 2(\sqrt{b^2 + c^2} - b)(\sqrt{b^2 + c^2} - c). \quad (5)$$

see also ARC

## Triangle Center

A triangle center is a point whose TRILINEAR COORDINATES are defined in terms of the side lengths and angles of a TRIANGLE. The function giving the coordinates  $\alpha : \beta : \gamma$  is called the TRIANGLE CENTER FUNCTION. The four ancient centers are the CENTROID, INCENTER, CIRCUMCENTER, and ORTHOCENTER. For a listing of these and other triangle centers, see Kimberling (1994).

A triangle center is said to be REGULAR IFF there is a TRIANGLE CENTER FUNCTION which is a POLYNOMIAL in  $\Delta$ ,  $a$ ,  $b$ , and  $c$  (where  $\Delta$  is the AREA of the TRIANGLE) such that the TRILINEAR COORDINATES of the center are

$$f(a, b, c) : f(b, c, a) : f(c, a, b).$$

A triangle center is said to be a MAJOR TRIANGLE CENTER if the TRIANGLE CENTER FUNCTION  $\alpha$  is a function of ANGLE  $A$  alone, and therefore  $\beta$  and  $\gamma$  of  $B$  and  $C$  alone, respectively.

see also MAJOR TRIANGLE CENTER, REGULAR TRIANGLE CENTER, TRIANGLE, TRIANGLE CENTER FUNCTION, TRILINEAR COORDINATES, TRILINEAR POLAR

## Triangle Center Function

A HOMOGENEOUS FUNCTION  $f(a, b, c)$ , i.e., a function  $f$  such that

$$f(ta, tb, tc) = t^n f(a, b, c),$$

which gives the TRILINEAR COORDINATES of a TRIANGLE CENTER as

$$\alpha : \beta : \gamma = f(a, b, c) : f(b, c, a) : f(c, a, b).$$

The variables may correspond to angles ( $A, B, C$ ) or side lengths ( $a, b, c$ ), since these can be interconverted using the LAW OF COSINES.

see also MAJOR TRIANGLE CENTER, REGULAR TRIANGLE CENTER, TRIANGLE CENTER, TRILINEAR COORDINATES

## Triangle Coefficient

A function of three variables written  $\Delta(abc) \equiv \Delta(a, b, c)$  and defined by

$$\Delta(abc) \equiv \sqrt{\frac{(a+b-c)!(a-b+c)!(-a+b+c)!}{(a+b+c+1)!}}.$$

## Triangle Condition

The condition that  $j$  takes on the values

$$j = j_1 + j_2, j_1 + j_2 - 1, \dots, |j_1 - j_2|,$$

denoted  $\Delta(j_1 j_2 j)$ .

**Triangle Counting**

Given rods of length 1, 2, ...,  $n$ , how many distinct triangles  $T(n)$  can be made? Lengths for which

$$l_i = l_j + l_k$$

obviously do not give triangles, but all other combinations of three rods do. The answer is

$$T(n) = \begin{cases} \frac{1}{24}n(n-2)(2n-5) & \text{for } n \text{ even} \\ \frac{1}{24}(n-1)(n-3)(2n-1) & \text{for } n \text{ odd.} \end{cases}$$

The values for  $n = 1, 2, \dots$  are 0, 0, 0, 1, 3, 7, 13, 22, 34, 50, ... (Sloane's A002623). Somewhat surprisingly, this sequence is also given by the GENERATING FUNCTION

$$f(x) = \frac{x^4}{(1-x)^3(1-x^2)} = x^4 + 3x^5 + 7x^6 + 13x^7 + \dots$$

**References**

**Triangle of Figurate Numbers**

see FIGURATE NUMBER TRIANGLE

**Triangle Function**

$$\Lambda(x) \equiv \begin{cases} 0 & |x| > 1 \\ 1 - |x| & |x| < 1 \end{cases} \quad (1)$$

$$= \Pi(x) * \Pi(x) \quad (2)$$

$$= \Pi(x) * H(x + \frac{1}{2}) - \Pi(x) * H(x - \frac{1}{2}), \quad (3)$$

where  $\Pi$  is the RECTANGLE FUNCTION and  $H$  is the HEAVISIDE STEP FUNCTION. An obvious generalization used as an APODIZATION FUNCTION goes by the name of the BARTLETT FUNCTION.

There is also a three-argument function known as the triangle function:

$$\lambda(x, y, z) \equiv x^2 + y^2 + z^2 - 2xy - 2xz - 2yz. \quad (4)$$

It follows that

$$\lambda(a^2, b^2, c^2) = (a+b+c)(a+b-c)(a-b+c)(a-b-c). \quad (5)$$

see also ABSOLUTE VALUE, BARTLETT FUNCTION, HEAVISIDE STEP FUNCTION, RAMP FUNCTION, SGN, TRIANGLE COEFFICIENT

**Triangle Inequality**

Let  $\mathbf{x}$  and  $\mathbf{y}$  be vectors

$$|\mathbf{x}| - |\mathbf{y}| \leq |\mathbf{x} + \mathbf{y}| \leq |\mathbf{x}| + |\mathbf{y}|. \quad (1)$$

Equivalently, for COMPLEX NUMBERS  $z_1$  and  $z_2$ ,

$$|z_1| - |z_2| \leq |z_1 + z_2| \leq |z_1| + |z_2|. \quad (2)$$

A generalization is

$$\left| \sum_{k=1}^n a_k \right| \leq \sum_{k=1}^n |a_k|. \quad (3)$$

see also p-ADIC NUMBER, STRONG TRIANGLE INEQUALITY

**Triangle Inscribing in a Circle**

Select three points at random on a unit CIRCLE. Find the distribution of possible areas. The first point can be assigned coordinates (1, 0) without loss of generality. Call the central angles from the first point to the second and third  $\theta_1$  and  $\theta_2$ . The range of  $\theta_1$  can be restricted to  $[0, \pi]$  because of symmetry, but  $\theta_2$  can range from  $[0, 2\pi)$ . Then

$$A(\theta_1, \theta_2) = 2 \left| \sin(\frac{1}{2}\theta_1) \sin(\frac{1}{2}\theta_2) \sin[\frac{1}{2}(\theta_1 - \theta_2)] \right|, \quad (1)$$

so

$$\bar{A} = \frac{\int_0^\pi \int_0^{2\pi} A(\theta_1, \theta_2) d\theta_2 d\theta_1}{C}, \quad (2)$$

where

$$C \equiv \int_0^\pi \int_0^{2\pi} d\theta_2 d\theta_1 = 2\pi^2. \quad (3)$$

Therefore,

$$\begin{aligned}
 \bar{A} &= \frac{2}{2\pi^2} \int_0^\pi \int_0^{2\pi} \left| \sin\left(\frac{1}{2}\theta_1\right) \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_1 - \theta_2)\right] \right| d\theta_2 d\theta_1 \\
 &= \frac{1}{\pi^2} \int_0^\pi \sin\left(\frac{1}{2}\theta_1\right) \left[ \int_0^{2\pi} \sin\left(\frac{1}{2}\theta_2\right) \left| \sin\left[\frac{1}{2}(\theta_2 - \theta_1)\right] \right| d\theta_2 \right] d\theta_1 \\
 &= \frac{1}{\pi^2} \int_0^\pi \int_{\theta_2 - \theta_1 > 0}^{2\pi} \sin\left(\frac{1}{2}\theta_1\right) \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_1 - \theta_2)\right] d\theta_2 d\theta_1 \\
 &\quad + \frac{1}{\pi^2} \int_0^\pi \int_{\theta_2 - \theta_1 < 0}^{2\pi} \sin\left(\frac{1}{2}\theta_1\right) \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_1 - \theta_2)\right] d\theta_2 d\theta_1 \\
 &= \frac{1}{\pi^2} \int_0^\pi \sin\left(\frac{1}{2}\theta_1\right) \left[ \int_{\theta_1}^{2\pi} \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_2 - \theta_1)\right] d\theta_2 \right] d\theta_1 \\
 &\quad + \frac{1}{\pi^2} \int_0^\pi \sin\left(\frac{1}{2}\theta_1\right) \left[ \int_0^{\theta_1} \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_2 - \theta_1)\right] d\theta_2 \right] d\theta_1. \quad (4)
 \end{aligned}$$

But

$$\begin{aligned}
 &\int \left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_2 - \theta_1)\right] d\theta_2 \\
 &= \int \sin\left(\frac{1}{2}\theta_2\right) \left[ \sin\left(\frac{1}{2}\theta_2\right) \cos\left(\frac{1}{2}\theta_2\right) - \sin\left(\frac{1}{2}\theta_1\right) \cos\left(\frac{1}{2}\theta_2\right) \right] d\theta_2 \\
 &= \cos\left(\frac{1}{2}\theta_1\right) \int \sin^2\left(\frac{1}{2}\theta_2\right) d\theta_2 - \sin\left(\frac{1}{2}\theta_1\right) \int \sin\left(\frac{1}{2}\theta_2\right) \cos\left(\frac{1}{2}\theta_2\right) d\theta_2 \\
 &= \frac{1}{2} \cos\left(\frac{1}{2}\theta_1\right) \int (1 - \cos\theta_2) d\theta_2 - \frac{1}{2} \sin\left(\frac{1}{2}\theta_2\right) \int \sin\theta_2 d\theta_2 \\
 &= \frac{1}{2} \cos\left(\frac{1}{2}\theta_1\right) (\theta_2 - \sin\theta_2) + \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) \cos(\theta_2). \quad (5)
 \end{aligned}$$

Write (4) as

$$\bar{A} = \frac{1}{\pi^2} \left[ \int_0^\pi \sin\left(\frac{1}{2}\theta_1\right) I_1 d\theta_1 + \int_0^\pi \sin\left(\frac{1}{2}\theta_1\right) I_2 d\theta_1 \right], \quad (6)$$

then

$$I_1 \equiv \int_{\theta_1}^{2\pi} \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_2 - \theta_1)\right] d\theta_2, \quad (7)$$

and

$$I_2 \equiv \int_0^{\theta_1} \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_1 - \theta_2)\right] d\theta_2. \quad (8)$$

From (6),

$$\begin{aligned}
 I_1 &= \frac{1}{2} \cos\left(\frac{1}{2}\theta_2\right) [\theta_2 - \sin\theta_2]_{\theta_1}^{2\pi} + \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) [\cos\theta_2]_{\theta_1}^{2\pi} \\
 &= \frac{1}{2} \cos\left(\frac{1}{2}\theta_1\right) (2\pi - \theta_1 + \sin\theta_1) \\
 &\quad + \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) (1 - \cos\theta_1) \\
 &= \pi \cos\left(\frac{1}{2}\theta_1\right) - \frac{1}{2}\theta_1 \cos\left(\frac{1}{2}\theta_1\right) + \frac{1}{2} [\cos\left(\frac{1}{2}\theta_1\right) \sin\theta_1 \\
 &\quad - \cos\theta_1 \sin\left(\frac{1}{2}\theta_1\right)] + \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) \\
 &= \pi \cos\left(\frac{1}{2}\theta_1\right) - \frac{1}{2}\theta_1 \cos\left(\frac{1}{2}\theta_1\right) + \frac{1}{2} + \frac{1}{2} \sin(\theta_1 - \frac{1}{2}\theta_1) \\
 &\quad + \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) \\
 &= \pi \cos\left(\frac{1}{2}\theta_1\right) - \frac{1}{2}\theta_1 \cos\left(\frac{1}{2}\theta_1\right) + \sin\left(\frac{1}{2}\theta_1\right), \quad (9)
 \end{aligned}$$

so

$$\int_0^\pi I_1 \sin\left(\frac{1}{2}\theta_1\right) d\theta_1 = \frac{5}{4}\pi. \quad (10)$$

Also,

$$\begin{aligned}
 I_2 &= \frac{1}{2} \cos\left(\frac{1}{2}\theta_1\right) [\sin\theta_2 - \theta_2]_0^{\theta_1} - \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) [\cos\theta_2]_0^{\theta_1} \\
 &= \frac{1}{2} \cos\left(\frac{1}{2}\theta_2\right) (\sin\theta_1 - \theta_1) - \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) (\cos\theta_1 - 1) \\
 &= -\frac{1}{2}\theta_1 \cos\left(\frac{1}{2}\theta_1\right) \\
 &\quad + \frac{1}{2} [\sin\theta_1 \cos\left(\frac{1}{2}\theta_1\right) - \cos\theta_1 \sin\left(\frac{1}{2}\theta_2\right)] \\
 &\quad + \frac{1}{2} \sin\left(\frac{1}{2}\theta_1\right) \\
 &= -\frac{1}{2}\theta_1 \cos\left(\frac{1}{2}\theta_1\right) + \sin\left(\frac{1}{2}\theta_1\right), \quad (11)
 \end{aligned}$$

so

$$\int_0^\pi I_2 \sin\left(\frac{1}{2}\theta_1\right) d\theta_1 = \frac{1}{4}\pi. \quad (12)$$

Combining (10) and (12) gives

$$\bar{A} = \frac{1}{\pi^2} \left( \frac{5\pi}{4} + \frac{\pi}{4} \right) = \frac{3}{2\pi} \approx 0.4775. \quad (13)$$

The VARIANCE is

$$\begin{aligned}
 \sigma_A^2 &= \frac{1}{2\pi^2} \int_0^\pi \int_0^{2\pi} [A(\theta_1, \theta_2) - \frac{3}{2\pi}]^2 d\theta_2 d\theta_1 \\
 &= \frac{1}{2\pi^2} \int_0^\pi \int_0^{2\pi} \left[ 2 \left| \sin\left(\frac{1}{2}\theta_1\right) \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_1 - \theta_2)\right] \right| \right. \\
 &\quad \left. - \frac{3}{2\pi} \right]^2 d\theta_2 d\theta_1 \\
 &= \frac{1}{2\pi^2} \int_0^\pi \int_0^{2\pi} \left\{ 4 \sin^2\left(\frac{1}{2}\theta_1\right) \sin^2\left(\frac{1}{2}\theta_2\right) \sin^2\left[\frac{1}{2}(\theta_2 - \theta_1)\right] \right. \\
 &\quad \left. - \frac{6}{\pi} \left| \sin\left(\frac{1}{2}\theta_1\right) \sin\left(\frac{1}{2}\theta_2\right) \sin\left[\frac{1}{2}(\theta_1 - \theta_2)\right] \right| + \frac{9}{4\pi^2} \right\} d\theta_2 d\theta_1 \\
 &= \frac{1}{2\pi^2} \left[ \int_0^\pi \pi (2 + \theta_1) \sin^2\left(\frac{1}{2}\theta_1\right) d\theta_1 \right. \\
 &\quad \left. - \frac{6}{\pi} \left( \frac{5\pi}{4} + \frac{\pi}{4} \right) + \frac{9}{4\pi^2} (2\pi^2) \right] \\
 &= \frac{1}{2\pi^2} \left( \frac{3\pi^2}{4} - 9 + \frac{9}{2} \right) = \frac{1}{2\pi^2} \left( \frac{3\pi^2}{4} - \frac{9}{2} \right) \\
 &= \frac{3(\pi^2 - 6)}{8\pi^2} \approx 0.1470. \quad (14)
 \end{aligned}$$

see also POINT-POINT DISTANCE—1-D, TETRAHEDRON INSCRIBING

### Triangle Inscribing in an Ellipse

To inscribe an EQUILATERAL TRIANGLE in an ELLIPSE, place the top VERTEX at  $(0, b)$ , then solve to find the  $(x, y)$  coordinate of the other two VERTICES.

$$\sqrt{x^2 + (b - y)^2} = 2x \quad (1)$$

$$x^2 + (b - y)^2 = 4x^2 \quad (2)$$

$$3x^2 = (b - y)^2. \quad (3)$$

Now plugging in the equation of the ELLIPSE

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \quad (4)$$

gives

$$3a^2 \left(1 - \frac{y^2}{b^2}\right) = b^2 - 2by + y^2 \quad (5)$$

$$y^2 \left(1 + 3\frac{a^2}{b^2}\right) - 2by + (b^2 - 3a^2) = 0 \quad (6)$$

$$y = \frac{2b - \sqrt{4b^2 - 4(b^2 - 3a^2)\left(1 + 3\frac{a^2}{b^2}\right)}}{2\left(1 + 3\frac{a^2}{b^2}\right)} \\ = \frac{1 - \sqrt{1 - \left(1 - 3\frac{a^2}{b^2}\right)\left(1 + 3\frac{a^2}{b^2}\right)}}{1 + 3\frac{a^2}{b^2}} b, \quad (7)$$

and

$$x = \pm a \sqrt{1 - \frac{y^2}{b^2}}. \quad (8)$$

### Triangle Postulate

The sum of the ANGLES of a TRIANGLE is two RIGHT ANGLES. This POSTULATE is equivalent to the PARALLEL AXIOM.

### Triangle Squaring

Let  $CD$  be the ALTITUDE of a TRIANGLE  $\triangle ABC$  and let  $E$  be its MIDPOINT. Then

$$\text{area}(\triangle ABC) = \frac{1}{2} AB \cdot CD = AB \cdot DE,$$

and  $\square A B F G$  can be squared by RECTANGLE SQUARING. The general POLYGON can be treated by drawing diagonals, squaring the constituent triangles, and then combining the squares together using the PYTHAGOREAN THEOREM.

see also PYTHAGOREAN THEOREM, RECTANGLE SQUARING

### Triangle Tiling

The total number of triangle (including inverted ones) in the above figures is given by

$$N(n) = \begin{cases} \frac{1}{8}n(n+2)(2n+1) & \text{for } n \text{ even} \\ \frac{1}{8}[n(n+2)(2n+1) - 1] & \text{for } n \text{ odd.} \end{cases}$$

The first few values are 1, 5, 13, 27, 48, 78, 118, 170, 235, 315, 411, 525, 658, 812, 988, 1188, 1413, 1665, ... (Sloane's A002717).

### Triangular Dipyramid

The triangular (or TRIGONAL) dipyramid is one of the convex DELTAHEDRA, and JOHNSON SOLID  $J_{12}$ .

see also DELTAHEDRON, DIPYRAMID, JOHNSON SOLID, PENTAGONAL DIPYRAMID

### Triangular Graph

The triangular graph with  $n$  nodes on a side is denoted  $T(n)$ . Tutte (1970) showed that the CHROMATIC POLYNOMIALS of planar triangular graphs possess a ROOT close to  $\phi^2 = 2.618033\dots$ , where  $\phi$  is the GOLDEN MEAN. More precisely, if  $n$  is the number of VERTICES of  $G$ , then

$$P_G(\phi^2) \leq \phi^{5-n}$$

(Le Lionnais 1983, p. 46). Every planar triangular graph possesses a VERTEX of degree 3, 4, or 5 (Le Lionnais 1983, pp. 49 and 53).

### Triangular Matrix

An upper triangular MATRIX  $U$  is defined by

$$U_{ij} = \begin{cases} a_{ij} & \text{for } i \leq j \\ 0 & \text{for } i > j. \end{cases} \quad (1)$$

Written explicitly,

$$U = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_{nn} \end{bmatrix}. \quad (2)$$

A lower triangular MATRIX  $L$  is defined by

$$L_{ij} = \begin{cases} a_{ij} & \text{for } i \geq j \\ 0 & \text{for } i < j. \end{cases} \quad (3)$$

Written explicitly,

$$L = \begin{bmatrix} a_{11} & 0 & \cdots & 0 \\ a_{21} & a_{22} & \cdots & 0 \\ \vdots & \vdots & \ddots & 0 \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}. \quad (4)$$

see also HESSENBERG MATRIX, HILBERT MATRIX, MATRIX, VANDERMONDE MATRIX

### Triangular Number

A FIGURATE NUMBER of the form  $T_n \equiv n(n+1)/2$  obtained by building up regular triangles out of dots. The first few triangle numbers are 1, 3, 6, 10, 15, 21, ... (Sloane's A000217).  $T_4 = 10$  gives the number and arrangement of BOWLING pins, while  $T_5 = 15$  gives the number and arrangement of balls in BILLIARDS. Triangular numbers satisfy the RECURRENCE RELATION

$$T_{n+1}^2 - T_n^2 = (n+1)^3, \quad (1)$$

as well as

$$3T_n + T_{n-1} = T_{2n} \quad (2)$$

$$3T_n + T_{n+1} = T_{2n+1} \quad (3)$$

$$1 + 3 + 5 + \cdots + (2n-1) = T_n + T_{n-1} \quad (4)$$

and

$$(2n+1)^2 = 8T + 1 = T_{n-1} + 6T_n + T_{n+1} \quad (5)$$

(Conway and Guy 1996). They have the simple GENERATING FUNCTION

$$f(x) = \frac{x}{(1-x)^3} = x + 3x^2 + 6x^3 + 10x^4 + 15x^5 + \cdots \quad (6)$$

Every triangular number is also a HEXAGONAL NUMBER, since

$$\frac{1}{2}r(r+1) = \begin{cases} \left(\frac{r+1}{2}\right) \left[2\left(\frac{r+1}{2}\right) - 1\right] & \text{for } r \text{ odd} \\ \left(-\frac{r}{2}\right) \left[2\left(-\frac{r}{2}\right) - 1\right] & \text{for } r \text{ even.} \end{cases} \quad (7)$$

Also, every PENTAGONAL NUMBER is  $1/3$  of a triangular number. The sum of consecutive triangular numbers is a SQUARE NUMBER, since

$$\begin{aligned} T_r + T_{r-1} &= \frac{1}{2}r(r+1) + \frac{1}{2}(r-1)r \\ &= \frac{1}{2}r[(r+1) + (r-1)] = r^2. \end{aligned} \quad (8)$$

Interesting identities involving triangular numbers and SQUARE NUMBERS are

$$\sum_{k=1}^{2n-1} (-1)^{k+1} T_k = n^2 \quad (9)$$

$$T_n^2 = \sum_{k=1}^n k^3 = \frac{1}{4}n^2(n+1)^2 \quad (10)$$

$$\sum_{k=1,3,\dots,q} k^3 = T_n \quad (11)$$

for  $q$  ODD and

$$n = \frac{1}{2}(q^2 + 2q - 1). \quad (12)$$

All EVEN PERFECT NUMBERS are triangular  $T_p$  with PRIME  $p$ . Furthermore, every EVEN PERFECT NUMBER  $P > 6$  is of the form

$$P = 1 + 9T_n = T_{3n+1}, \quad (13)$$

where  $T_n$  is a triangular number with  $n = 8j + 2$  (Eaton 1995, 1996). Therefore, the nested expression

$$9(9 \cdots (9(9(9T_n + 1) + 1) + 1) \cdots + 1) + 1 \quad (14)$$

generates triangular numbers for any  $T_n$ . An INTEGER  $k$  is a triangular number IFF  $8k + 1$  is a SQUARE NUMBER  $> 1$ .

The numbers 1, 36, 1225, 41616, 1413721, 48024900, ... (Sloane's A001110) are SQUARE TRIANGULAR NUMBERS, i.e., numbers which are simultaneously triangular and SQUARE (Pietenpol 1962). Numbers which are simultaneously triangular and TETRAHEDRAL satisfy the BINOMIAL COEFFICIENT equation

$$\binom{n}{2} = \binom{m}{3}, \quad (15)$$

the only solutions of which are  $(m, n) = (10, 16)$ ,  $(22, 56)$ , and  $(36, 120)$  (Guy 1994, p. 147).

The smallest of two INTEGERS for which  $n^3 - 13$  is four times a triangular number is 5 (Cesaro 1886; Le Lionnais 1983, p. 56). The only FIBONACCI NUMBERS which are triangular are 1, 3, 21, and 55 (Ming 1989), and the only

PELL NUMBER which is triangular is 1 (McDaniel 1996). The BEAST NUMBER 666 is triangular, since

$$T_{6.6} = T_{36} = 666. \quad (16)$$

In fact, it is the largest REPDIGIT triangular number (Bellew and Weger 1975-76).

FERMAT'S POLYGONAL NUMBER THEOREM states that every POSITIVE INTEGER is a sum of *most* three TRIANGULAR NUMBERS, four SQUARE NUMBERS, five PENTAGONAL NUMBERS, and  $n$   $n$ -POLYGONAL NUMBERS. Gauss proved the triangular case, and noted the event in his diary on July 10, 1796, with the notation

$$**EYRHK A \quad num = \Delta + \Delta + \Delta. \quad (17)$$

This case is equivalent to the statement that every number of the form  $8m + 3$  is a sum of three ODD SQUARES (Duke 1997). Dirichlet derived the number of ways in which an INTEGER  $m$  can be expressed as the sum of three triangular numbers (Duke 1997). The result is particularly simple for a PRIME of the form  $8m + 3$ , in which case it is the number of squares mod  $8m + 3$  minus the number of nonsquares mod  $8m + 3$  in the INTERVAL  $4m + 1$  (Deligne 1973).

The only triangular numbers which are the PRODUCT of three consecutive INTEGERS are 6, 120, 210, 990, 185136, 258474216 (Guy 1994, p. 148).

## Triangular Symmetry Group

(2, 3, 3)

(2, 3, 4)

(2, 3, 5)

Given a TRIANGLE with angles  $(\pi/p, \pi/q, \pi/r)$ , the resulting symmetry GROUP is called a  $(p, q, r)$  triangle group (also known as a SPHERICAL TESSELLATION). In 3-D, such GROUPS must satisfy

$$\frac{1}{p} + \frac{1}{q} + \frac{1}{r} > 1,$$

and so the only solutions are  $(2, 2, n)$ ,  $(2, 3, 3)$ ,  $(2, 3, 4)$ , and  $(2, 3, 5)$  (Ball and Coxeter 1987). The group  $(2, 3, 6)$  gives rise to the semiregular planar TESSELLATIONS of types 1, 2, 5, and 7. The group  $(2, 3, 7)$  gives hyperbolic tessellations.

## Triangulation

Triangulation is the division of a surface into a set of TRIANGLES, usually with the restriction that each TRIANGLE side is entirely shared by two adjacent TRIANGLES. It was proved in 1930 that every surface has a triangulation, but it might require an infinite number of TRIANGLES. A surface with a finite number of triangles in its triangulation is called COMPACT. B. Chazelle showed that an arbitrary SIMPLE POLYGON can be triangulated in linear time.

## Tribonacci Number

The tribonacci numbers are a generalization of the FIBONACCI NUMBERS defined by  $T_1 = 1$ ,  $T_2 = 1$ ,  $T_3 = 2$ , and the RECURRENCE RELATION

$$T_n = T_{n-1} + T_{n-2} + T_{n-3} \quad (1)$$

for  $n \geq 4$ . They represent the  $n = 3$  case of the FIBONACCI  $n$ -STEP NUMBERS. The first few terms are 1, 1, 2, 4, 7, 13, 24, 44, 81, 149, ... (Sloane's A000073). The ratio of adjacent terms tends to 1.83929, which is the REAL ROOT of  $x^3 - x^2 - x - 1 = 0$ . The Tribonacci numbers can also be computed using the GENERATING FUNCTION

$$\frac{1}{1 - z - z^2 - z^3} = 1 + z + 2z^2 + 4z^3 + 7z^4 + 13z^5 + 24z^6 + 44z^7 + 81z^8 + 149z^9 + \dots \quad (2)$$

An explicit FORMULA for  $T_n$  is also given by

$$\left[ 3 \frac{\left\{ \frac{1}{3}(19+3\sqrt{33})^{1/3} + \frac{1}{3}(19-3\sqrt{33})^{1/3} + \frac{1}{3} \right\}^n (586+102\sqrt{33})^{1/3}}{(586+102\sqrt{33})^{2/3} + 4 - 2(586+102\sqrt{33})^{1/3}} \right], \quad (3)$$

where  $[x]$  denotes the NINT function (Plouffe). The first part of a NUMERATOR is related to the REAL root of  $x^3 - x^2 - x - 1$ , but determination of the DENOMINATOR requires an application of the LLL ALGORITHM. The numbers increase asymptotically to

$$T_n \sim c^n, \quad (4)$$

where

$$c = \left( \frac{19}{27} + \frac{1}{9}\sqrt{33} \right)^{1/3} + \frac{4}{9} \left( \frac{19}{27} + \frac{1}{9}\sqrt{33} \right)^{-1/3} + \frac{1}{3} = 1.83928675521 \dots \quad (5)$$

(Plouffe).

see also FIBONACCI  $n$ -STEP NUMBER, FIBONACCI NUMBER, TETRANACCI NUMBER

## References

## Trichotomy Law

Every REAL NUMBER is NEGATIVE, 0, or POSITIVE.

## Tricolorable

A projection of a LINK is tricolorable if each of the strands in the projection can be colored in one of three different colors such that, at each crossing, all three colors come together or only one does and at least two different colors are used. The TREFOIL KNOT and trivial 2-link are tricolorable, but the UNKNOT, WHITEHEAD LINK, and FIGURE-OF-EIGHT KNOT are not.

If the projection of a knot is tricolorable, then REIDEMEISTER MOVES on the knot preserve tricolorability, so either every projection of a knot is tricolorable or none is.

## Tridecagon

A 13-sided POLYGON, sometimes also called the TRISKAIDECAGON.

## Trident

The plane curve given by the equation

$$xy = x^3 - a^3.$$

see also TRIDENT OF DESCARTES, TRIDENT OF NEWTON

**Trident of Descartes**

The plane curve given by the equation

$$(a+x)(a-x)(2a-x) = x^3 - 2ax^2 - a^2x + 2a^3 = axy$$

$$y = \frac{(a+x)(a-x)(2a-x)}{ax}$$

The above plot has  $a = 2$ .

**Trident of Newton**

The CUBIC CURVE defined by

$$ax^3 + bx^2 + cx + d = xy$$

with  $a \neq 0$ . The curve cuts the axis in either one or three points. It was the 66th curve in Newton's classification of CUBICS. Newton stated that the curve has four infinite legs and that the  $y$ -axis is an ASYMPTOTE to two tending toward contrary parts.

**Tridiagonal Matrix**

A MATRIX with NONZERO elements only on the diagonal and slots horizontally or vertically adjacent the diagonal. A general  $4 \times 4$  tridiagonal MATRIX has the form

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 \\ 0 & a_{32} & a_{33} & a_{34} \\ 0 & 0 & a_{43} & a_{44} \end{bmatrix}.$$

Inversion of such a matrix requires only  $n$  (as opposed to  $n^3$ ) arithmetic operations (Acton 1990).

## Trigonometric Substitution

INTEGRALS of the form

$$\int f(\cos \theta, \sin \theta) d\theta \quad (1)$$

can be solved by making the substitution  $z = e^{i\theta}$  so that  $dz = ie^{i\theta} d\theta$  and expressing

$$\cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2} = \frac{z + z^{-1}}{2} \quad (2)$$

$$\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i} = \frac{z - z^{-1}}{2i}. \quad (3)$$

The integral can then be solved by CONTOUR INTEGRATION.

Alternatively, making the substitution  $t \equiv \tan(\theta/2)$  transforms (1) into

$$\int f\left(\frac{2t}{1+t^2}, \frac{1-t^2}{1+t^2}\right) \frac{2dt}{1+t^2}. \quad (4)$$

The following table gives trigonometric substitutions which can be used to transform integrals involving square roots.

Form	Substitution
$\sqrt{a^2 - x^2}$	$x = a \sin \theta$
$\sqrt{a^2 + x^2}$	$x = a \tan \theta$
$\sqrt{x^2 - a^2}$	$x = a \sec \theta$

see also HYPERBOLIC SUBSTITUTION

## Trigonometry

The study of ANGLES and of the angular relationships of planar and 3-D figures is known as trigonometry. The trigonometric functions (also called the CIRCULAR FUNCTIONS) comprising trigonometry are the COSECANT  $\csc x$ , COSINE  $\cos x$ , COTANGENT  $\cot x$ , SECANT  $\sec x$ , SINE  $\sin x$ , and TANGENT  $\tan x$ . The inverses of these functions are denoted  $\csc^{-1} x$ ,  $\cos^{-1} x$ ,  $\cot^{-1} x$ ,  $\sec^{-1} x$ ,  $\sin^{-1} x$ , and  $\tan^{-1} x$ . Note that the  $f^{-1}$  NOTATION here means INVERSE FUNCTION, not  $f$  to the  $-1$  POWER.

The trigonometric functions are most simply defined using the UNIT CIRCLE. Let  $\theta$  be an ANGLE measured counterclockwise from the  $x$ -AXIS along an ARC of the CIRCLE. Then  $\cos \theta$  is the horizontal coordinate of the ARC endpoint, and  $\sin \theta$  is the vertical component. The RATIO  $\sin \theta / \cos \theta$  is defined as  $\tan \theta$ . As a result of this

definition, the trigonometric functions are periodic with period  $2\pi$ , so

$$\text{func}(2\pi n + \theta) = \text{func}(\theta), \quad (1)$$

where  $n$  is an INTEGER and  $\text{func}$  is a trigonometric function.

From the PYTHAGOREAN THEOREM,

$$\sin^2 \theta + \cos^2 \theta = 1. \quad (2)$$

Therefore, it is also true that

$$\tan^2 \theta + 1 = \sec^2 \theta \quad (3)$$

$$1 + \cot^2 \theta = \csc^2 \theta. \quad (4)$$

The trigonometric functions can be defined algebraically in terms of COMPLEX EXPONENTIALS (i.e., using the EULER FORMULA) as

$$\sin z \equiv \frac{e^{iz} - e^{-iz}}{2i} \quad (5)$$

$$\csc z \equiv \frac{1}{\sin z} = \frac{2i}{e^{iz} - e^{-iz}} \quad (6)$$

$$\cos z \equiv \frac{e^{iz} + e^{-iz}}{2} \quad (7)$$

$$\sec z \equiv \frac{1}{\cos z} = \frac{2}{e^{iz} + e^{-iz}} \quad (8)$$

$$\tan z \equiv \frac{\sin z}{\cos z} = \frac{e^{iz} - e^{-iz}}{i(e^{iz} + e^{-iz})} \quad (9)$$

$$\cot z \equiv \frac{1}{\tan z} = \frac{i(e^{iz} + e^{-iz})}{e^{iz} - e^{-iz}} = \frac{i(1 + e^{-2iz})}{1 - e^{-2iz}}. \quad (10)$$

OSBORNE'S RULE gives a prescription for converting trigonometric identities to analogous identities for HYPERBOLIC FUNCTIONS.

The ANGLES  $n\pi/m$  (with  $m, n$  integers) for which the trigonometric function may be expressed in terms of finite root extraction of *real numbers* are limited to values of  $m$  which are precisely those which produce constructible POLYGONS. Gauss showed these to be of the form

$$m = 2^k p_1 p_2 \cdots p_s, \quad (11)$$

where  $k$  is an INTEGER  $\geq 0$  and the  $p_i$  are distinct FERMAT PRIMES. The first few values are  $m = 1, 2, 3, 4, 5, 6, 8, 10, 12, 15, 16, 17, 20, \dots$  (Sloane's A003401). Although formulas for trigonometric functions may be found analytically for other  $m$  as well, the expressions involve ROOTS OF COMPLEX NUMBERS obtained by solving a CUBIC, QUARTIC, or higher order equation. The cases  $m = 7$  and  $m = 9$  involve the CUBIC EQUATION and QUARTIC EQUATION, respectively. A partial table of the analytic values of SINE, COSINE, and TANGENT for arguments  $\pi/m$  is given below. Derivations of these formulas appear in the following entries.

$^\circ$	rad	$\sin x$	$\cos x$	$\tan x$
0.0	0	0	1	0
15.0	$\frac{1}{12}\pi$	$\frac{1}{4}(\sqrt{6} - \sqrt{2})$	$\frac{1}{4}(\sqrt{6} + \sqrt{2})$	$2 - \sqrt{3}$
18.0	$\frac{1}{10}\pi$	$\frac{1}{4}(\sqrt{5} - 1)$	$\frac{1}{4}\sqrt{10 + 2\sqrt{5}}$	$\frac{1}{5}\sqrt{25 - 10\sqrt{5}}$
22.5	$\frac{1}{8}\pi$	$\frac{1}{2}\sqrt{2 - \sqrt{2}}$	$\frac{1}{2}\sqrt{2 + \sqrt{2}}$	$\sqrt{2} - 1$
30.0	$\frac{1}{6}\pi$	$\frac{1}{2}$	$\frac{1}{2}\sqrt{3}$	$\frac{1}{3}\sqrt{3}$
36.0	$\frac{1}{5}\pi$	$\frac{1}{4}\sqrt{10 - 2\sqrt{5}}$	$\frac{1}{4}(1 + \sqrt{5})$	$\sqrt{5 - 2\sqrt{5}}$
45.0	$\frac{1}{4}\pi$	$\frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{2}$	1
60.0	$\frac{1}{3}\pi$	$\frac{1}{2}\sqrt{3}$	$\frac{1}{2}$	$\sqrt{3}$
90.0	$\frac{1}{2}\pi$	1	0	$\infty$
180.0	$\pi$	0	-1	0

The INVERSE TRIGONOMETRIC FUNCTIONS are generally defined on the following domains.

Function	Domain
$\sin^{-1} x$	$-\frac{1}{2}\pi \leq y \leq \frac{1}{2}\pi$
$\cos^{-1} x$	$0 \leq y \leq \pi$
$\tan^{-1} x$	$-\frac{1}{2}\pi < y < \frac{1}{2}\pi$
$\csc^{-1} x$	$0 \leq y \leq \frac{1}{2}\pi$ or $\pi \leq y \leq \frac{3}{2}\pi$
$\sec^{-1} x$	$0 \leq y \leq \pi$
$\cot^{-1} x$	$0 \leq y \leq \frac{1}{2}\pi$ or $-\pi \leq y \leq -\frac{1}{2}\pi$

Inverse-forward identities are

$$\tan^{-1}(\cot x) = \frac{1}{2}\pi - x \quad (12)$$

$$\sin^{-1}(\cos x) = \frac{1}{2}\pi - x \quad (13)$$

$$\sec^{-1}(\csc x) = \frac{1}{2}\pi - x, \quad (14)$$

and forward-inverse identities are

$$\cos(\sin^{-1} x) = \sqrt{1 - x^2} \quad (15)$$

$$\cos(\tan^{-1} x) = \frac{1}{\sqrt{1 + x^2}} \quad (16)$$

$$\sin(\cos^{-1} x) = \sqrt{1 - x^2}$$

$$\sin(\tan^{-1} x) = \frac{x}{\sqrt{1 + x^2}} \quad (17)$$

$$\tan(\cos^{-1} x) = \frac{\sqrt{1 - x^2}}{x} \quad (18)$$

$$\tan(\sin^{-1} x) = \frac{x}{\sqrt{1 - x^2}}. \quad (19)$$

Inverse sum identities include

$$\sin^{-1} x + \cos^{-1} x = \frac{1}{2}\pi \quad (20)$$

$$\tan^{-1} x + \cot^{-1} x = \frac{1}{2}\pi \quad (21)$$

$$\sec^{-1} x + \csc^{-1} x = \frac{1}{2}\pi, \quad (22)$$

where (20) follows from

$$x = \sin(\sin^{-1} x) = \cos(\frac{1}{2}\pi - \sin^{-1} x). \quad (23)$$

Complex inverse identities in terms of LOGARITHMS include

$$\sin^{-1}(z) = -i \ln(iz \pm \sqrt{1 - z^2}) \quad (24)$$

$$\cos^{-1}(z) = -i \ln(z \pm i\sqrt{1 - z^2}) \quad (25)$$

$$\tan^{-1}(z) = -i \ln \left( \frac{1 + iz}{\sqrt{1 + z^2}} \right) \quad (26)$$

$$= \frac{1}{2} i \ln \left( \frac{1 - iz}{1 + iz} \right). \quad (27)$$

For IMAGINARY arguments,

$$\sin(iz) = i \sinh z \quad (28)$$

$$\cos(iz) = \cosh z. \quad (29)$$

For COMPLEX arguments,

$$\sin(x + iy) = \sin x \cosh y + i \cos x \sinh y \quad (30)$$

$$\cos(x + iy) = \cos x \cosh y - i \sin x \sinh y. \quad (31)$$

For the ABSOLUTE SQUARE of COMPLEX arguments  $z = x + iy$ ,

$$|\sin(x + iy)|^2 = \sin^2 x + \sinh^2 y \quad (32)$$

$$|\cos(x + iy)|^2 = \cos^2 x + \sinh^2 y. \quad (33)$$

The MODULUS also satisfies the curious identity

$$|\sin(x + iy)| = |\sin x + \sin(iy)|. \quad (34)$$

The only functions satisfying identities of this form,

$$|f(x + iy)| = |f(x) + f(iy)| \quad (35)$$

are  $f(z) = Az$ ,  $f(z) = A \sin(bz)$ , and  $f(z) = A \sinh(bz)$  (Robinson 1957).

Trigonometric product formulas can be derived using the following figure (Kung 1996).

In the figure,

$$\theta = \frac{1}{2}(\alpha - \beta) \quad (36)$$

$$\gamma = \frac{1}{2}(\alpha + \beta), \quad (37)$$

so

$$s = \frac{1}{2}(\sin \alpha + \sin \beta) = \cos\left[\frac{1}{2}(\alpha - \beta)\right] \sin\left[\frac{1}{2}(\alpha + \beta)\right] \quad (38)$$

$$t = \frac{1}{2}(\cos \alpha + \cos \beta) = \cos\left[\frac{1}{2}(\alpha - \beta)\right] \cos\left[\frac{1}{2}(\alpha + \beta)\right]. \quad (39)$$

With  $\theta$  and  $\gamma$  as previously defined, the above figure (Kung 1996) gives

$$u = \cos \beta - \cos \alpha = 2 \sin\left[\frac{1}{2}(\alpha - \beta)\right] \sin\left[\frac{1}{2}(\alpha + \beta)\right] \quad (40)$$

$$v = \sin \alpha - \sin \beta = 2 \sin\left[\frac{1}{2}(\alpha - \beta)\right] \cos\left[\frac{1}{2}(\alpha + \beta)\right]. \quad (41)$$

Angle addition FORMULAS express trigonometric functions of sums of angles  $\alpha \pm \beta$  in terms of functions of  $\alpha$  and  $\beta$ . They can be simply derived using COMPLEX exponentials and the EULER FORMULA,

$$\begin{aligned} \sin(\alpha + \beta) &= \frac{e^{i(\alpha + \beta)} - e^{-i(\alpha + \beta)}}{2i} = \frac{e^{i\alpha}e^{i\beta} - e^{-i\alpha}e^{-i\beta}}{2i} \\ &= \frac{(\cos \alpha + i \sin \alpha)(\cos \beta + i \sin \beta)}{2i} \\ &\quad - \frac{(\cos \alpha - i \sin \alpha)(\cos \beta - i \sin \beta)}{2i} \\ &= \frac{\cos \alpha \cos \beta + i \sin \beta \cos \alpha + i \sin \alpha \cos \beta - \sin \alpha \sin \beta}{2i} \\ &\quad + \frac{-\cos \alpha \cos \beta + i \cos \alpha \sin \beta + i \sin \alpha \cos \beta + \sin \alpha \sin \beta}{2i} \\ &= \sin \alpha \cos \beta + \sin \beta \cos \alpha \end{aligned} \quad (42)$$

$$\begin{aligned} \cos(\alpha + \beta) &= \frac{e^{i(\alpha + \beta)} + e^{-i(\alpha + \beta)}}{2} = \frac{e^{i\alpha}e^{i\beta} + e^{-i\alpha}e^{-i\beta}}{2} \\ &= \frac{(\cos \alpha + i \sin \alpha)(\cos \beta + i \sin \beta)}{2} \\ &\quad + \frac{(\cos \alpha - i \sin \alpha)(\cos \beta - i \sin \beta)}{2} \\ &= \frac{\cos \alpha \cos \beta + i \cos \alpha \sin \beta + i \sin \alpha \cos \beta - \sin \alpha \sin \beta}{2} \\ &\quad + \frac{\cos \alpha \cos \beta - i \cos \alpha \sin \beta - i \sin \alpha \cos \beta - \sin \alpha \sin \beta}{2} \\ &= \cos \alpha \cos \beta - \sin \alpha \sin \beta. \end{aligned} \quad (43)$$

Taking the ratio gives the tangent angle addition FORMULA

$$\begin{aligned}\tan(\alpha+\beta) &\equiv \frac{\sin(\alpha+\beta)}{\cos(\alpha+\beta)} = \frac{\sin \alpha \cos \beta + \sin \beta \cos \alpha}{\cos \alpha \cos \beta - \sin \alpha \sin \beta} \\ &= \frac{\frac{\sin \alpha}{\cos \alpha} + \frac{\sin \beta}{\cos \beta}}{1 - \frac{\sin \alpha \sin \beta}{\cos \alpha \cos \beta}} = \frac{\tan \alpha + \tan \beta}{1 - \tan \alpha \tan \beta}. \quad (44)\end{aligned}$$

The angle addition FORMULAS can also be derived purely algebraically without the use of COMPLEX NUMBERS. Consider the following figure.

From the large RIGHT TRIANGLE,

$$\sin(\alpha + \beta) = \frac{L \sin \beta + a}{L \cos \alpha + b} \quad (45)$$

$$\cos(\alpha + \beta) = \frac{L \cos \beta}{L \cos \alpha + b}. \quad (46)$$

But, from the small triangle (inset at upper right),

$$a = \frac{L \sin \alpha}{\cos(\alpha + \beta)} \quad (47)$$

$$b = L \sin \alpha \tan(\alpha + \beta). \quad (48)$$

Plugging  $a$  and  $b$  from (47) and (48) into (45) and (46) gives

$$\begin{aligned}\sin(\alpha + \beta) &= \frac{L \sin \beta + \frac{L \sin \alpha}{\cos(\alpha + \beta)}}{L \cos \alpha + \frac{L \sin \alpha \sin(\alpha + \beta)}{\cos(\alpha + \beta)}} \\ &= \frac{\sin \beta \cos(\alpha + \beta) + \sin \alpha}{\cos \alpha \cos(\alpha + \beta) + \sin \alpha \sin(\alpha + \beta)}, \quad (49)\end{aligned}$$

and

$$\begin{aligned}\cos(\alpha + \beta) &= \frac{L \cos \beta}{L \cos \alpha + \frac{L \sin \alpha \sin(\alpha + \beta)}{\cos(\alpha + \beta)}} \\ &= \frac{\cos \beta}{\cos \alpha + \frac{\sin \alpha \sin(\alpha + \beta)}{\cos(\alpha + \beta)}}. \quad (50)\end{aligned}$$

Now solve (50) for  $\cos(\alpha + \beta)$ ,

$$\cos(\alpha + \beta) \cos \alpha + \sin \alpha \sin(\alpha + \beta) = \cos \beta \quad (51)$$

to obtain

$$\cos(\alpha + \beta) = \frac{\cos \beta - \sin \alpha \sin(\alpha + \beta)}{\cos \alpha}. \quad (52)$$

Plugging (52) into (49) gives

$$\begin{aligned}\sin(\alpha + \beta) &= \frac{\sin \beta \left[ \frac{\cos \beta - \sin \alpha \sin(\alpha + \beta)}{\cos \alpha} \right] + \sin \alpha}{\cos \alpha \left[ \frac{\cos \beta - \sin \alpha \sin(\alpha + \beta)}{\cos \alpha} \right] + \sin \alpha \sin(\alpha + \beta)} \\ &= \frac{\sin \beta \cos \beta - \sin \alpha \sin \beta \sin(\alpha + \beta) + \sin \alpha \cos \alpha}{\cos \alpha \cos \beta - \sin \alpha \cos \alpha \sin(\alpha + \beta) + \sin \alpha \cos \alpha \sin(\alpha + \beta)} \\ &= \frac{\sin \beta \cos \beta - \sin \alpha \sin \beta \sin(\alpha + \beta) + \sin \alpha \cos \alpha}{\cos \alpha \cos \beta} \\ &= \frac{\sin \alpha \cos \alpha + \sin \beta \cos \beta}{\cos \alpha \cos \beta} - \frac{\sin \alpha \sin \beta}{\cos \alpha \cos \beta} \sin(\alpha + \beta), \quad (53)\end{aligned}$$

so

$$\sin(\alpha + \beta) \left( 1 + \frac{\sin \alpha \sin \beta}{\cos \alpha \cos \beta} \right) = \frac{\sin \alpha \cos \alpha + \sin \beta \cos \beta}{\cos \alpha \cos \beta} \quad (54)$$

$$\begin{aligned}\sin(\alpha + \beta)(\cos \alpha \cos \beta + \sin \alpha \sin \beta) \\ = \sin \alpha \cos \alpha + \sin \beta \cos \beta, \quad (55)\end{aligned}$$

and

$$\begin{aligned}\sin(\alpha + \beta) &= \frac{\sin \alpha \cos \alpha + \sin \beta \cos \beta}{\sin \alpha \sin \beta + \cos \alpha \cos \beta} \\ &= \frac{\sin \alpha \cos \alpha + \sin \beta \cos \beta}{\sin \alpha \sin \beta + \cos \alpha \cos \beta} \cdot \frac{\sin \alpha \cos \beta + \sin \beta \cos \alpha}{\sin \alpha \cos \beta + \sin \beta \cos \alpha}. \quad (56)\end{aligned}$$

Multiplying out the DENOMINATOR gives

$$\begin{aligned}(\cos \alpha \cos \beta + \sin \alpha \sin \beta)(\sin \alpha \cos \beta + \sin \beta \cos \alpha) \\ = \sin \alpha \cos \alpha \cos^2 \beta + \cos^2 \alpha \sin \beta \cos \beta \\ + \sin^2 \alpha \sin \beta \cos \beta + \sin \alpha \cos \alpha \sin^2 \beta \\ = \sin \alpha \cos \alpha + \sin \beta \cos \beta, \quad (57)\end{aligned}$$

so

$$\sin(\alpha + \beta) = \sin \alpha \cos \beta + \sin \beta \cos \alpha. \quad (58)$$

Multiplying out (50),

$$\cos(\alpha + \beta) \cos \alpha + \sin \alpha \sin(\alpha + \beta) = \cos \beta \quad (59)$$

$$\begin{aligned}\cos(\alpha + \beta) &= \frac{\cos \beta - \sin \alpha \sin(\alpha + \beta)}{\cos \alpha} \\ &= \frac{\cos \beta - \sin \alpha (\sin \alpha \cos \beta + \sin \beta \cos \alpha)}{\cos \alpha} \\ &= \frac{\cos \beta (1 - \sin^2 \alpha) + \sin \alpha \cos \alpha \sin \beta}{\cos \alpha} \\ &= \frac{\cos^2 \alpha \cos \beta + \sin \alpha \cos \alpha \sin \beta}{\cos \alpha} \\ &= \cos \alpha \cos \beta + \sin \alpha \sin \beta. \quad (60)\end{aligned}$$

Summarizing,

$$\sin(\alpha + \beta) = \sin \alpha \cos \beta + \sin \beta \cos \alpha \quad (61)$$

$$\sin(\alpha - \beta) = \sin \alpha \cos \beta - \sin \beta \cos \alpha \quad (62)$$

$$\cos(\alpha + \beta) = \cos \alpha \cos \beta - \sin \alpha \sin \beta \quad (63)$$

$$\cos(\alpha - \beta) = \cos \alpha \cos \beta + \sin \alpha \sin \beta \quad (64)$$

$$\tan(\alpha + \beta) = \frac{\tan \alpha + \tan \beta}{1 - \tan \alpha \tan \beta} \quad (65)$$

$$\tan(\alpha - \beta) = \frac{\tan \alpha - \tan \beta}{1 + \tan \alpha \tan \beta}. \quad (66)$$

The sine and cosine angle addition identities can be summarized by the MATRIX EQUATION

$$\begin{bmatrix} \cos x & \sin x \\ -\sin x & \cos x \end{bmatrix} \begin{bmatrix} \cos y & \sin y \\ -\sin y & \cos y \end{bmatrix} = \begin{bmatrix} \cos(x+y) & \sin(x+y) \\ -\sin(x+y) & \cos(x+y) \end{bmatrix}. \quad (67)$$

The double angle formulas are

$$\sin(2\alpha) = 2 \sin \alpha \cos \alpha \quad (68)$$

$$\cos(2\alpha) = \cos^2 \alpha - \sin^2 \alpha \quad (69)$$

$$= 2 \cos^2 \alpha - 1 \quad (70)$$

$$= 1 - 2 \sin^2 \alpha \quad (71)$$

$$\tan(2\alpha) = \frac{2 \tan \alpha}{1 - \tan^2 \alpha}. \quad (72)$$

General multiple angle formulas are

$$\sin(n\alpha) = 2 \sin[(n-1)\alpha] \cos \alpha - \sin[(n-2)\alpha] \quad (73)$$

$$\begin{aligned} \sin(nx) &= n \cos^{n-1} x \sin x \\ &\quad - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} \cos^{n-3} x \sin^3 x + \dots \end{aligned} \quad (74)$$

$$\cos(n\alpha) = 2 \cos[(n-1)\alpha] \cos \alpha - \cos[(n-2)\alpha] \quad (75)$$

$$\begin{aligned} \cos(nx) &= \cos^n x - \frac{n(n-1)}{1 \cdot 2} \cos^{n-2} x \sin^2 x \\ &\quad + \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} \cos^{n-4} x \sin^4 x - \dots \end{aligned} \quad (76)$$

$$\tan(n\alpha) = \frac{\tan[(n-1)\alpha] + \tan \alpha}{1 - \tan[(n-1)\alpha] \tan \alpha}. \quad (77)$$

Therefore, any trigonometric function of a sum can be broken up into a sum of trigonometric functions with  $\sin \alpha \cos \alpha$  cross terms. Particular cases for multiple angle formulas up to  $n = 4$  are given below.

$$\sin(3\alpha) = 3 \sin \alpha - 4 \sin^3 \alpha \quad (78)$$

$$\cos(3\alpha) = 4 \cos^3 \alpha - 3 \cos \alpha \quad (79)$$

$$\tan(3\alpha) = \frac{3 \tan \alpha - \tan^3 \alpha}{1 - 3 \tan^2 \alpha} \quad (80)$$

$$\sin(4\alpha) = 4 \sin \alpha \cos \alpha - 8 \sin^3 \alpha \cos \alpha \quad (81)$$

$$\cos(4\alpha) = 8 \cos^4 \alpha - 8 \cos^2 \alpha + 1 \quad (82)$$

$$\tan(4\alpha) = \frac{4 \tan \alpha - 4 \tan^3 \alpha}{1 - 6 \tan^2 \alpha + \tan^4 \alpha}. \quad (83)$$

Beyer (1987, p. 139) gives formulas up to  $n = 6$ .

Sum identities include

$$\begin{aligned} \frac{\tan(\alpha - \beta)}{\tan(\alpha + \beta)} &= \frac{\sin(\alpha - \beta) \cos(\alpha + \beta)}{\cos(\alpha - \beta) \sin(\alpha + \beta)} \\ &= \frac{(\sin \alpha \cos \beta - \sin \beta \cos \alpha)(\cos \alpha \cos \beta - \sin \alpha \sin \beta)}{(\cos \alpha \cos \beta + \sin \alpha \sin \beta)(\sin \alpha \cos \beta + \sin \beta \cos \alpha)} \\ &= \frac{\sin \alpha \cos \alpha - \sin \beta \cos \beta}{\sin \alpha \cos \alpha + \sin \beta \cos \beta}. \end{aligned} \quad (84)$$

Infinite sum identities include

$$\sum_{k=1, 3, 5, \dots}^{\infty} \frac{e^{-kx} \sin(ky)}{k} = \frac{1}{2} \tan^{-1} \left( \frac{\sin y}{\sinh x} \right). \quad (85)$$

Trigonometric half-angle formulas include

$$\sin \left( \frac{\alpha}{2} \right) = \sqrt{\frac{1 - \cos \alpha}{2}} \quad (86)$$

$$\cos \left( \frac{\alpha}{2} \right) = \sqrt{\frac{1 + \cos \alpha}{2}} \quad (87)$$

$$\tan \left( \frac{\alpha}{2} \right) = \frac{\sin \alpha}{1 + \cos \alpha} \quad (88)$$

$$= \frac{1 - \cos \alpha}{\sin \alpha} \quad (89)$$

$$= \frac{1 \pm \sqrt{1 + \tan^2 \alpha}}{\tan \alpha} \quad (90)$$

$$= \frac{\tan \alpha \sin \alpha}{\tan \alpha + \sin \alpha}. \quad (91)$$

The PROSTHAPHAERESIS FORMULAS are

$$\sin \alpha + \sin \beta = 2 \sin \left[ \frac{1}{2}(\alpha + \beta) \right] \cos \left[ \frac{1}{2}(\alpha - \beta) \right] \quad (92)$$

$$\sin \alpha - \sin \beta = 2 \cos \left[ \frac{1}{2}(\alpha + \beta) \right] \sin \left[ \frac{1}{2}(\alpha - \beta) \right] \quad (93)$$

$$\sin \alpha + \cos \beta = 2 \cos \left[ \frac{1}{2}(\alpha + \beta) \right] \cos \left[ \frac{1}{2}(\alpha - \beta) \right] \quad (94)$$

$$\cos \alpha - \cos \beta = -2 \sin \left[ \frac{1}{2}(\alpha + \beta) \right] \sin \left[ \frac{1}{2}(\alpha - \beta) \right]. \quad (95)$$

Related formulas are

$$\sin \alpha \cos \beta = \frac{1}{2} [\sin(\alpha - \beta) + \sin(\alpha + \beta)] \quad (96)$$

$$\cos \alpha \cos \beta = \frac{1}{2} [\cos(\alpha - \beta) + \cos(\alpha + \beta)] \quad (97)$$

$$\cos \alpha \sin \beta = \frac{1}{2} [\sin(\alpha + \beta) - \sin(\alpha - \beta)] \quad (98)$$

$$\sin \alpha \sin \beta = \frac{1}{2} [\cos(\alpha - \beta) - \cos(\alpha + \beta)]. \quad (99)$$

Multiplying both sides by 2 gives the equations sometimes known as the WERNER FORMULAS.

Trigonometric product/sum formulas are

$$\sin(\alpha + \beta) \sin(\alpha - \beta) = \sin^2 \alpha - \sin^2 \beta = \cos^2 \beta - \cos^2 \alpha \quad (100)$$

$$\cos(\alpha + \beta) \cos(\alpha - \beta) = \cos^2 \alpha - \sin^2 \beta = \cos^2 \beta - \sin^2 \alpha. \quad (101)$$

Power formulas include

$$\sin^2 x = \frac{1}{2}[1 - \cos(2x)] \quad (102)$$

$$\sin^3 x = \frac{1}{4}[3 \sin x - \sin(3x)] \quad (103)$$

$$\sin^4 x = \frac{1}{8}[3 - 4 \cos(2x) + \cos(4x)] \quad (104)$$

and

$$\cos^2 x = \frac{1}{2}[1 + \cos(2x)] \quad (105)$$

$$\cos^3 x = \frac{1}{4}[3 \cos x + \cos(3x)] \quad (106)$$

$$\cos^4 x = \frac{1}{8}[3 + 4 \cos(2x) + \cos(4x)] \quad (107)$$

(Beyer 1987, p. 140). Formulas of these types can also be given analytically as

$$\sin^{2n} x = \frac{1}{2^{2n}} \binom{2n}{n} + \frac{(-1)^n}{2^{2n-1}} \sum_{k=0}^{n-1} (-1)^k \binom{2n}{k} \cos[2(n-k)x] \quad (108)$$

$$\sin^{2n+1} x = \frac{(-1)^n}{4^n} \sum_{k=0}^n (-1)^k \binom{2n+1}{k} \sin[(2n+1-2k)x] \quad (109)$$

$$\cos^{2n} x = \frac{(-1)^n}{2^{2n}} \binom{2n}{n} + \frac{1}{2^{2n-1}} \sum_{k=0}^{n-1} \binom{2n}{k} \cos[2(n-k)x] \quad (110)$$

$$\cos^{2n+1} x = \frac{1}{4^n} \sum_{k=0}^n \binom{2n+1}{k} \cos[(2n+1-2k)x] \quad (111)$$

(Kogan), where  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT.

#### Trigonometry Values— $\pi$

By the definition of the trigonometric functions,

$$\sin \pi = 0 \quad (1)$$

$$\cos \pi = -1 \quad (2)$$

$$\tan \pi = 0 \quad (3)$$

$$\csc \pi = \infty \quad (4)$$

$$\sec \pi = -1 \quad (5)$$

$$\cot \pi = \infty. \quad (6)$$

#### Trigonometry Values— $\pi/2$

By the definition of the trigonometric functions,

$$\sin \left( \frac{\pi}{2} \right) = 1 \quad (1)$$

$$\cos \left( \frac{\pi}{2} \right) = 0 \quad (2)$$

$$\tan \left( \frac{\pi}{2} \right) = \infty \quad (3)$$

$$\csc \left( \frac{\pi}{2} \right) = 1 \quad (4)$$

$$\sec \left( \frac{\pi}{2} \right) = \infty \quad (5)$$

$$\cot \left( \frac{\pi}{2} \right) = 0. \quad (6)$$

see also DIGON

**Trigonometry Values— $\pi/3$** From TRIGONOMETRY VALUES:  $\pi/6$ 

$$\sin\left(\frac{\pi}{6}\right) = \frac{1}{2} \quad (1)$$

$$\cos\left(\frac{\pi}{6}\right) = \frac{1}{2}\sqrt{3} \quad (2)$$

together with the trigonometric identity

$$\sin(2\alpha) = 2 \sin \alpha \cos \alpha, \quad (3)$$

the identity

$$\sin\left(\frac{\pi}{3}\right) = 2 \sin\left(\frac{\pi}{6}\right) \cos\left(\frac{\pi}{6}\right) = 2\left(\frac{1}{2}\right)\left(\frac{1}{2}\sqrt{3}\right) = \frac{1}{2}\sqrt{3} \quad (4)$$

is obtained. Using the identity

$$\cos(2\alpha) = 1 - 2 \sin^2 \alpha, \quad (5)$$

then gives

$$\cos\left(\frac{\pi}{3}\right) = 1 - 2 \sin^2\left(\frac{\pi}{6}\right) = 1 - 2\left(\frac{1}{2}\right)^2 = \frac{1}{2}. \quad (6)$$

Summarizing,

$$\sin\left(\frac{\pi}{3}\right) = \frac{1}{2}\sqrt{3} \quad (7)$$

$$\cos\left(\frac{\pi}{3}\right) = \frac{1}{2} \quad (8)$$

$$\tan\left(\frac{\pi}{3}\right) = \sqrt{3}. \quad (9)$$

*see also* EQUILATERAL TRIANGLE**Trigonometry Values— $\pi/4$** 

For a RIGHT ISOSCELES TRIANGLE, symmetry requires that the angle at each VERTEX be given by

$$\frac{1}{2}\pi + 2\alpha = \pi, \quad (1)$$

so  $\alpha = \pi/4$ . The sides are equal, so

$$\sin^2 \alpha + \cos^2 \alpha = 2 \sin^2 \alpha = 1. \quad (2)$$

Solving,

$$\sin\left(\frac{\pi}{4}\right) = \frac{1}{2}\sqrt{2} \quad (3)$$

$$\cos\left(\frac{\pi}{4}\right) = \frac{1}{2}\sqrt{2} \quad (4)$$

$$\tan\left(\frac{\pi}{4}\right) = 1. \quad (5)$$

*see also* SQUARE**Trigonometry Values— $\pi/5$** 

Use the identity

$$\sin(5\alpha) = 5 \sin \alpha - 20 \sin^3 \alpha + 16 \sin^5 \alpha. \quad (1)$$

Now, let  $\alpha \equiv \pi/5$  and  $x \equiv \sin \alpha$ . Then

$$\sin \pi = 0 = 5x - 20x^3 + 16x^5 \quad (2)$$

$$16x^4 - 20x^2 + 5 = 0. \quad (3)$$

Solving the QUADRATIC EQUATION for  $x^2$  gives

$$\begin{aligned} \sin^2\left(\frac{\pi}{5}\right) = x^2 &= \frac{20 \pm \sqrt{(-20)^2 - 4 \cdot 16 \cdot 5}}{2 \cdot 16} \\ &= \frac{20 \pm \sqrt{80}}{32} = \frac{1}{8}(5 \pm \sqrt{5}). \end{aligned} \quad (4)$$

Now,  $\sin(\pi/5)$  must be less than

$$\sin\left(\frac{\pi}{4}\right) = \frac{1}{2}\sqrt{2}, \quad (5)$$

so taking the MINUS SIGN and simplifying gives

$$\sin\left(\frac{\pi}{5}\right) = \sqrt{\frac{5 - \sqrt{5}}{8}} = \frac{1}{4}\sqrt{10 - 2\sqrt{5}}. \quad (6)$$

 $\cos(\pi/5)$  can be computed from

$$\cos\left(\frac{\pi}{5}\right) = \sqrt{1 - \sin^2\left(\frac{\pi}{5}\right)} = \frac{1}{4}(1 + \sqrt{5}). \quad (7)$$

Summarizing,

$$\sin\left(\frac{\pi}{5}\right) = \frac{1}{4}\sqrt{10 - 2\sqrt{5}} \quad (8)$$

$$\sin\left(\frac{2\pi}{5}\right) = \frac{1}{4}\sqrt{10 + 2\sqrt{5}} \quad (9)$$

$$\sin\left(\frac{3\pi}{5}\right) = \frac{1}{4}\sqrt{10 + 2\sqrt{5}} \quad (10)$$

$$\sin\left(\frac{4\pi}{5}\right) = \frac{1}{4}\sqrt{10 - 2\sqrt{5}} \quad (11)$$

$$\cos\left(\frac{\pi}{5}\right) = \frac{1}{4}(1 + \sqrt{5}) \quad (12)$$

$$\cos\left(\frac{2\pi}{5}\right) = \frac{1}{4}(-1 + \sqrt{5}) \quad (13)$$

$$\cos\left(\frac{3\pi}{5}\right) = \frac{1}{4}(1 - \sqrt{5}) \quad (14)$$

$$\cos\left(\frac{4\pi}{5}\right) = -\frac{1}{4}(1 + \sqrt{5}) \quad (15)$$

$$\tan\left(\frac{\pi}{5}\right) = \sqrt{5 - 2\sqrt{5}} \quad (16)$$

$$\tan\left(\frac{2\pi}{5}\right) = \sqrt{5 + 2\sqrt{5}} \quad (17)$$

$$\tan\left(\frac{3\pi}{5}\right) = -\sqrt{5 + 2\sqrt{5}} \quad (18)$$

$$\tan\left(\frac{4\pi}{5}\right) = -\sqrt{5 - 2\sqrt{5}}. \quad (19)$$

*see also* DODECAHEDRON, ICOSAHEDRON, PENTAGON, PENTAGRAM

**Trigonometry Values— $\pi/6$** 

Given a RIGHT TRIANGLE with angles defined to be  $\alpha$  and  $2\alpha$ , it must be true that

$$\alpha + 2\alpha + \frac{1}{2}\pi = \pi, \quad (1)$$

so  $\alpha = \pi/6$ . Define the hypotenuse to have length 1 and the side opposite  $\alpha$  to have length  $x$ , then the side opposite  $2\alpha$  has length  $\sqrt{1-x^2}$ . This gives  $\sin \alpha \equiv x$  and

$$\sin(2\alpha) = \sqrt{1-x^2}. \quad (2)$$

But

$$\sin(2\alpha) = 2 \sin \alpha \cos \alpha = 2x\sqrt{1-x^2}, \quad (3)$$

so we have

$$\sqrt{1-x^2} = 2x\sqrt{1-x^2}. \quad (4)$$

This gives  $2x = 1$ , or

$$\sin\left(\frac{\pi}{6}\right) = \frac{1}{2}. \quad (5)$$

$\cos(\pi/6)$  is then computed from

$$\cos\left(\frac{\pi}{6}\right) = \sqrt{1 - \sin^2\left(\frac{\pi}{6}\right)} = \sqrt{1 - \left(\frac{1}{2}\right)^2} = \frac{1}{2}\sqrt{3}. \quad (6)$$

Summarizing,

$$\sin\left(\frac{\pi}{6}\right) = \frac{1}{2} \quad (7)$$

$$\cos\left(\frac{\pi}{6}\right) = \frac{1}{2}\sqrt{3} \quad (8)$$

$$\tan\left(\frac{\pi}{6}\right) = \frac{1}{3}\sqrt{3}. \quad (9)$$

see also HEXAGON, HEXAGRAM

**Trigonometry Values— $\pi/7$** 

Trigonometric functions of  $n\pi/7$  for  $n$  an integer cannot be expressed in terms of sums, products, and finite root extractions on *real* rational numbers because 7 is not a FERMAT PRIME. This also means that the HEPTAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\sin(n\alpha) = 2 \sin[(n-1)\alpha] \cos \alpha - \sin[(n-2)\alpha]. \quad (1)$$

The case  $n = 7$  gives

$$\begin{aligned} \sin(7\alpha) &= 2 \sin(6\alpha) \cos \alpha - \sin(5\alpha) \\ &= 2(32 \cos^5 \alpha \sin \alpha - 32 \cos^3 \alpha \sin \alpha + 6 \cos \alpha \sin \alpha) \cos \alpha \\ &\quad - (5 \sin \alpha - 20 \sin^3 \alpha + 16 \sin^5 \alpha) \\ &= 64 \cos^6 \alpha \sin \alpha - 64 \cos^4 \alpha \sin \alpha + 12 \cos^2 \alpha \sin \alpha \\ &\quad - 5 \sin \alpha + 20(1 - \cos^2 \alpha) \sin \alpha \\ &\quad - 16(1 - 2 \cos^2 \alpha + \cos^4 \alpha) \sin \alpha \\ &= \sin \alpha (64 \cos^6 \alpha - 80 \cos^4 \alpha + 24 \cos^2 \alpha - 1). \end{aligned} \quad (2)$$

Rewrite this using the identity  $\cos^2 \alpha = 1 - \sin^2 \alpha$ ,

$$\begin{aligned} \sin\left(\frac{\pi}{7}\right) &= \sin \alpha (7 - 56 \sin^2 \alpha + 112 \sin^4 \alpha - 64 \sin^6 \alpha) \\ &= -64 \sin \alpha (\sin^6 \alpha - \frac{112}{64} \sin^4 \alpha + \frac{56}{64} \sin^2 \alpha - \frac{7}{64}). \end{aligned} \quad (3)$$

Now, let  $\alpha \equiv \pi/7$  and  $x \equiv \sin^2 \alpha$ , then

$$\sin(\pi) = 0 = x^3 - \frac{7}{4}x^2 + \frac{7}{8}x - \frac{7}{64}, \quad (4)$$

which is a CUBIC EQUATION in  $x$ . The ROOTS are numerically found to be  $x \approx 0.188255, 0.611260, \dots, 0.950484, \dots$ . But  $\sin \alpha = \sqrt{x}$ , so these ROOTS correspond to  $\sin \alpha \approx 0.4338, \sin(2\alpha) \approx 0.7817, \sin(3\alpha) \approx 0.9749$ . By NEWTON'S RELATION

$$\prod_i r_i = -a_0, \quad (5)$$

we have

$$x_1 x_2 x_3 = \frac{7}{64}, \quad (6)$$

or

$$\sin\left(\frac{\pi}{7}\right) \sin\left(\frac{2\pi}{7}\right) \sin\left(\frac{3\pi}{7}\right) = \sqrt{\frac{7}{64}} = \frac{1}{8}\sqrt{7}. \quad (7)$$

Similarly,

$$\cos\left(\frac{\pi}{7}\right) \cos\left(\frac{2\pi}{7}\right) \cos\left(\frac{3\pi}{7}\right) = \frac{1}{8}. \quad (8)$$

The constants of the CUBIC EQUATION are given by

$$Q \equiv \frac{1}{9}(3a_1 - a_2^2) = \frac{1}{9}\left[3 \cdot \frac{7}{8} - \left(-\frac{7}{4}\right)^2\right] = -\frac{7}{144} \quad (9)$$

$$\begin{aligned} R &\equiv \frac{1}{54}(9a_2a_1 - 2a_2^3 - 27a_0) \\ &= \frac{1}{54}\left[9\left(-\frac{7}{4}\right)\left(\frac{1}{8}\right) - 2\left(-\frac{7}{4}\right)^3 - 27\left(-\frac{7}{64}\right)\right] \\ &= -\frac{7}{3456}. \end{aligned} \quad (10)$$

The DISCRIMINANT is then

$$\begin{aligned} D &\equiv Q^3 + R^2 = -\frac{343}{2,985,984} + \frac{49}{11,943,936} \\ &= -\frac{49}{442,368} < 0, \end{aligned} \quad (11)$$

so there are three distinct REAL ROOTS. Finding the first one,

$$x = \sqrt[3]{R + \sqrt{D}} + \sqrt[3]{R - \sqrt{D}} - \frac{1}{3}a_2. \quad (12)$$

Writing

$$\sqrt{D} = 3^{-3/2} \frac{7}{128} i, \quad (13)$$

plugging in from above, and anticipating that the solution we have picked corresponds to  $\sin(3\pi/7)$ ,

$$\begin{aligned}
\sin\left(\frac{3\pi}{7}\right) &= \sqrt{x} = \\
&\sqrt{\sqrt[3]{-\frac{7}{3456} + 3^{-3/2}\frac{7}{128}i} + \sqrt[3]{-\frac{7}{3456} - 3^{-3/2}\frac{7}{128}i} - \frac{1}{3}\left(-\frac{7}{4}\right)} \\
&= \sqrt{\sqrt[3]{-\frac{7}{3456} + 3^{-3/2}\frac{7}{128}i} + \sqrt[3]{-\frac{7}{3456} - 3^{-3/2}\frac{7}{128}i} + \frac{7}{12}} \\
&= \sqrt{\sqrt[3]{\frac{7}{3456}(-1 + 3^{3/2}i)} - \sqrt[3]{\frac{7}{3456}(1 + 3^{3/2}i)} + \frac{7}{12}} \\
&= \sqrt{\frac{1}{12}\left[\sqrt[3]{\frac{7}{2}(-1 + 3^{3/2}i)} - \sqrt[3]{\frac{7}{2}(1 + 3^{3/2}i)} + 7\right]}. \quad (14)
\end{aligned}$$

see also HEPTAGON

### Trigonometry Values— $\pi/8$

$$\begin{aligned}
\sin\left(\frac{\pi}{8}\right) &= \sin\left(\frac{1}{2} \cdot \frac{\pi}{4}\right) = \sqrt{\frac{1}{2}\left(1 - \cos\frac{\pi}{4}\right)} \\
&= \sqrt{\frac{1}{2}(1 - \frac{1}{2}\sqrt{2})} = \frac{1}{2}\sqrt{2 - \sqrt{2}}. \quad (1)
\end{aligned}$$

Now, checking to see if the SQUARE ROOT can be simplified gives

$$a^2 - b^2c = 2^2 - 1^2 \cdot 2 = 4 - 2 = 2, \quad (2)$$

which is not a PERFECT SQUARE, so the above expression cannot be simplified. Similarly,

$$\begin{aligned}
\cos\left(\frac{\pi}{8}\right) &= \cos\left(\frac{1}{2}\frac{\pi}{4}\right) = \sqrt{\frac{1}{2}\left(1 + \cos\frac{\pi}{4}\right)} \\
&= \sqrt{\frac{1}{2}\left(1 + \frac{\sqrt{2}}{2}\right)} = \frac{1}{2}\sqrt{2 + \sqrt{2}} \quad (3)
\end{aligned}$$

$$\begin{aligned}
\tan\left(\frac{\pi}{8}\right) &= \sqrt{\frac{2 - \sqrt{2}}{2 + \sqrt{2}}} = \sqrt{\frac{(2 - \sqrt{2})^2}{4 - 2}} = \sqrt{\frac{4 + 2 - 4\sqrt{2}}{2}} \\
&= \sqrt{\frac{6 - 4\sqrt{2}}{2}} = \sqrt{3 - 2\sqrt{2}}. \quad (4)
\end{aligned}$$

But

$$a^2 - b^2c = 3^2 - 2^2 \cdot 2 = 9 - 8 = 1 \quad (5)$$

is a PERFECT SQUARE, so we can find

$$d = \frac{1}{2}(3 \pm 1) = 1, 2.$$

Rewrite the above as

$$\tan\left(\frac{\pi}{8}\right) = \sqrt{2} - 1 \quad (6)$$

$$\cot\left(\frac{\pi}{8}\right) = \frac{1}{\sqrt{2} - 1} = \frac{\sqrt{2} + 1}{2 - 1} = \sqrt{2} + 1. \quad (7)$$

Summarizing,

$$\sin\left(\frac{\pi}{8}\right) = \frac{1}{2}\sqrt{2 - \sqrt{2}} \quad (8)$$

$$\sin\left(\frac{3\pi}{8}\right) = \frac{1}{2}\sqrt{2 + \sqrt{2}} \quad (9)$$

$$\cos\left(\frac{\pi}{8}\right) = \frac{1}{2}\sqrt{2 + \sqrt{2}} \quad (10)$$

$$\cos\left(\frac{3\pi}{8}\right) = \frac{1}{2}\sqrt{2 - \sqrt{2}} \quad (11)$$

$$\tan\left(\frac{\pi}{8}\right) = \sqrt{2} - 1 \quad (12)$$

$$\tan\left(\frac{3\pi}{8}\right) = \sqrt{2} + 1. \quad (13)$$

see also OCTAGON

### Trigonometry Values— $\pi/9$

Trigonometric functions of  $n\pi/9$  radians for  $n$  an integer not divisible by 3 (e.g.,  $40^\circ$  and  $80^\circ$ ) cannot be expressed in terms of sums, products, and finite root extractions on *real* rational numbers because 9 is not a product of distinct FERMAT PRIMES. This also means that the NONAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\sin(3\alpha) = 3\sin\alpha - 4\sin^3\alpha. \quad (1)$$

Let  $\alpha \equiv \pi/9$  and  $x \equiv \sin\alpha$ . Then the above identity gives the CUBIC EQUATION

$$4x^3 - 3x + \frac{1}{2}\sqrt{3} = 0 \quad (2)$$

$$x^3 - \frac{3}{4}x = -\frac{1}{8}\sqrt{3}. \quad (3)$$

This cubic is of the form

$$x^3 + px = q, \quad (4)$$

where

$$p = -\frac{3}{4} \quad (5)$$

$$q = -\frac{1}{8}\sqrt{3}. \quad (6)$$

The DISCRIMINANT is then

$$\begin{aligned}
D &\equiv \left(\frac{p}{3}\right)^3 + \left(\frac{q}{2}\right)^2 \\
&= \left(-\frac{1}{4}\right)^3 + \left(\frac{\sqrt{3}}{16}\right)^2 = -\frac{1}{16 \cdot 4} + \frac{3}{16 \cdot 16} = \frac{-4 + 3}{256} \\
&= -\frac{1}{256} < 0. \quad (7)
\end{aligned}$$

There are therefore three REAL distinct roots, which are approximately  $-0.9848$ ,  $0.3240$ , and  $0.6428$ . We want the one in the first QUADRANT, which is  $0.3240$ .

$$\begin{aligned}\sin\left(\frac{\pi}{9}\right) &= \sqrt[3]{-\frac{\sqrt{3}}{16} + \sqrt{-\frac{1}{256}}} + \sqrt[3]{-\frac{\sqrt{3}}{16} - \sqrt{-\frac{1}{256}}} \\ &= \sqrt[3]{-\frac{\sqrt{3}}{16} + \frac{1}{16}i} - \sqrt[3]{\frac{\sqrt{3}}{16} + \frac{1}{16}i} \\ &= 2^{-4/3}(\sqrt[3]{i - \sqrt{3}} - \sqrt[3]{i + \sqrt{3}}) \\ &\approx 0.3240 \dots\end{aligned}\quad (8)$$

Similarly,

$$\begin{aligned}\cos\left(\frac{\pi}{9}\right) &= 2^{-4/3}(\sqrt[3]{1 + i\sqrt{3}} + \sqrt[3]{1 - i\sqrt{3}}) \\ &\approx 0.7660 \dots\end{aligned}\quad (9)$$

Because of the NEWTON'S RELATIONS, we have the identities

$$\sin\left(\frac{\pi}{9}\right) \sin\left(\frac{2\pi}{9}\right) \sin\left(\frac{4\pi}{9}\right) = \frac{1}{8} \quad (10)$$

$$\cos\left(\frac{\pi}{9}\right) \cos\left(\frac{2\pi}{9}\right) \cos\left(\frac{4\pi}{9}\right) = \frac{1}{8}\sqrt{3} \quad (11)$$

$$\tan\left(\frac{\pi}{9}\right) \tan\left(\frac{2\pi}{9}\right) \tan\left(\frac{4\pi}{9}\right) = \sqrt{3}. \quad (12)$$

see also NONAGON, STAR OF GOLIATH

### Trigonometry Values— $\pi/10$

$$\begin{aligned}\sin\left(\frac{\pi}{10}\right) &= \sin\left(\frac{1}{2} \cdot \frac{\pi}{5}\right) = \sqrt{\frac{1}{2}\left[1 - \cos\left(\frac{\pi}{5}\right)\right]} \\ &= \sqrt{\frac{1}{2}\left[1 - \frac{1}{4}(1 + \sqrt{5})\right]} = \frac{1}{4}(\sqrt{5} - 1).\end{aligned}\quad (1)$$

So we have

$$\begin{aligned}\cos\left(\frac{\pi}{10}\right) &= \cos\left(\frac{1}{2} \cdot \frac{\pi}{5}\right) = \sqrt{\frac{1}{2}\left[1 + \cos\left(\frac{\pi}{5}\right)\right]} \\ &= \sqrt{\frac{1}{2}\left[1 + \frac{1}{4}(1 + \sqrt{5})\right]} \\ &= \frac{1}{4}\sqrt{10 + 2\sqrt{5}},\end{aligned}\quad (2)$$

and

$$\tan\left(\frac{\pi}{10}\right) = \sqrt{\frac{3 - \sqrt{5}}{5 + \sqrt{5}}} = \frac{1}{5}\sqrt{25 - 10\sqrt{5}}. \quad (3)$$

Summarizing,

$$\sin\left(\frac{\pi}{10}\right) = \frac{1}{4}(\sqrt{5} - 1) \quad (4)$$

$$\cos\left(\frac{\pi}{10}\right) = \frac{1}{4}\sqrt{10 + 2\sqrt{5}} \quad (5)$$

$$\tan\left(\frac{\pi}{10}\right) = \frac{1}{5}\sqrt{25 - 10\sqrt{5}} \quad (6)$$

$$\sin\left(\frac{3\pi}{10}\right) = \frac{1}{4}(1 + \sqrt{5}) \quad (7)$$

$$\cos\left(\frac{3\pi}{10}\right) = \frac{1}{4}(10 - 2\sqrt{5}) \quad (8)$$

$$\tan\left(\frac{3\pi}{10}\right) = \frac{1}{5}\sqrt{25 + 10\sqrt{5}}. \quad (9)$$

An interesting near-identity is given by

$$\frac{1}{4}\left[\cos\left(\frac{1}{10}\right) + \cosh\left(\frac{1}{10}\right) + 2\cos\left(\frac{1}{20}\sqrt{2}\right)\cosh\left(\frac{1}{20}\sqrt{2}\right)\right] \approx 1. \quad (10)$$

In fact, the left-hand side is approximately equal to  $1 + 2.480 \times 10^{-13}$ .

see also DECAGON, DECAGRAM

### Trigonometry Values— $\pi/11$

Trigonometric functions of  $n\pi/11$  for  $n$  an integer cannot be expressed in terms of sums, products, and finite root extractions on *real* rational numbers because 11 is not a FERMAT PRIME. This also means that the UNDECAGON is not a CONSTRUCTIBLE POLYGON.

However, exact expressions involving roots of *complex* numbers can still be derived using the trigonometric identity

$$\begin{aligned}\sin(11\alpha) &= \sin(12\alpha - \alpha) \cos \alpha - \cos(12\alpha) \sin \alpha \\ &= 2 \sin(6\alpha) \cos(6\alpha) \cos \alpha - [1 - 2 \sin^2(6\alpha)] \sin \alpha.\end{aligned}\quad (1)$$

Using the identities from Beyer (1987, p. 139),

$$\sin(6\alpha) = \sin \alpha \cos \alpha [32 \cos^4 \alpha - 32 \cos^2 \alpha + 6] \quad (2)$$

$$\cos(6\alpha) = 32 \cos^6 \alpha - 48 \cos^4 \alpha + 18 \cos^2 \alpha - 1 \quad (3)$$

gives

$$\begin{aligned}\sin(11\alpha) &= 2 \cos^2 \alpha \sin \alpha [32 \cos^4 \alpha - 32 \cos^2 \alpha + 6] \\ &\quad \times (32 \cos^6 \alpha - 48 \cos^4 \alpha + 18 \cos^2 \alpha - 1) \\ &\quad - \sin \alpha [1 - 2 \sin^2 \alpha \cos^2 \alpha (32 \cos^4 \alpha - 32 \cos^2 \alpha + 6)^2] \\ &= \sin \alpha (11 - 220 \sin^2 \alpha + 1232 \sin^4 \alpha \\ &\quad - 2816 \sin^6 \alpha + 2816 \sin^8 \alpha - 1024 \sin^{10} \alpha).\end{aligned}\quad (4)$$

Now, let  $\alpha \equiv \pi/11$  and  $x \equiv \sin^2 \alpha$ , then

$$\begin{aligned}\sin \pi &= 0 \\ &= 11 - 220x + 1232x^2 - 2816x^3 + 2816x^4 - 1024x^5.\end{aligned}\quad (5)$$

This equation is an irreducible QUINTIC EQUATION, so an analytic solution involving FINITE ROOT extractions does not exist. The numerical ROOTS are  $x = 0.07937, 0.29229, 0.57115, 0.82743, 0.97974$ . So  $\sin \alpha = 0.2817$ ,  $\sin(2\alpha) = 0.5406$ ,  $\sin(3\alpha) = 0.7557$ ,  $\sin(4\alpha) = 0.9096$ ,  $\sin(5\alpha) = 0.9898$ . From one of NEWTON'S IDENTITIES,

$$\sin\left(\frac{\pi}{11}\right) \sin\left(\frac{2\pi}{11}\right) \sin\left(\frac{3\pi}{11}\right) \sin\left(\frac{4\pi}{11}\right) \sin\left(\frac{5\pi}{11}\right) = \sqrt{\frac{11}{1024}} = \frac{\sqrt{11}}{32} \quad (6)$$

$$\cos\left(\frac{\pi}{11}\right) \cos\left(\frac{2\pi}{11}\right) \cos\left(\frac{3\pi}{11}\right) \cos\left(\frac{4\pi}{11}\right) \cos\left(\frac{5\pi}{11}\right) = \frac{1}{32} \quad (7)$$

$$\tan\left(\frac{\pi}{11}\right) \tan\left(\frac{2\pi}{11}\right) \tan\left(\frac{3\pi}{11}\right) \tan\left(\frac{4\pi}{11}\right) \tan\left(\frac{5\pi}{11}\right) = \sqrt{11}. \quad (8)$$

The trigonometric functions of  $\pi/11$  also obey the identity

$$\tan\left(\frac{3\pi}{11}\right) + 4 \sin\left(\frac{2\pi}{11}\right) = \sqrt{11}. \quad (9)$$

#### Trigonometry Values— $\pi/12$

$$\begin{aligned} \sin\left(\frac{\pi}{12}\right) &= \sin\left(\frac{\pi}{3} - \frac{\pi}{4}\right) \\ &= -\sin\left(\frac{\pi}{4}\right) \cos\left(\frac{\pi}{3}\right) + \sin\left(\frac{\pi}{3}\right) \cos\left(\frac{\pi}{4}\right) \\ &= -\frac{1}{2}\sqrt{2}\left(\frac{1}{2}\right) + \frac{1}{2}\sqrt{3}\left(\frac{1}{2}\sqrt{2}\right) \\ &= \frac{1}{4}(\sqrt{6} - \sqrt{2}). \end{aligned} \quad (1)$$

Similarly,

$$\begin{aligned} \cos\left(\frac{\pi}{12}\right) &= \cos\left(\frac{\pi}{3} - \frac{\pi}{4}\right) \\ &= \cos\left(\frac{\pi}{4}\right) \cos\left(\frac{\pi}{3}\right) + \sin\left(\frac{\pi}{3}\right) \sin\left(\frac{\pi}{4}\right) \\ &= \frac{1}{2}\left(\frac{1}{2}\sqrt{2}\right) + \frac{1}{2}\sqrt{3}\left(-\frac{1}{2}\sqrt{2}\right) \\ &= \frac{1}{4}(\sqrt{6} + \sqrt{2}). \end{aligned} \quad (2)$$

Summarizing,

$$\sin\left(\frac{\pi}{12}\right) = \frac{1}{4}(\sqrt{6} - \sqrt{2}) \approx 0.25881 \quad (3)$$

$$\cos\left(\frac{\pi}{12}\right) = \frac{1}{4}(\sqrt{6} + \sqrt{2}) \approx 0.96592 \quad (4)$$

$$\tan\left(\frac{\pi}{12}\right) = 2 - \sqrt{3} \approx 0.26794 \quad (5)$$

$$\csc\left(\frac{\pi}{12}\right) = \sqrt{6} + \sqrt{2} \approx 3.86370 \quad (6)$$

$$\sec\left(\frac{\pi}{12}\right) = \sqrt{6} - \sqrt{2} \approx 1.03527 \quad (7)$$

$$\cot\left(\frac{\pi}{12}\right) = 2 + \sqrt{3} \approx 3.73205. \quad (8)$$

#### Trigonometry Values— $\pi/15$

$$\begin{aligned} \sin\left(\frac{\pi}{15}\right) &= \sin\left(\frac{\pi}{6} - \frac{\pi}{10}\right) \\ &= \sin\left(\frac{\pi}{6}\right) \cos\left(\frac{\pi}{10}\right) - \sin\left(\frac{\pi}{10}\right) \cos\left(\frac{\pi}{6}\right) \\ &= \frac{1}{2} \sqrt{\frac{1}{8}(5 + \sqrt{5})} - \frac{\sqrt{3}}{2} \frac{1}{4}(\sqrt{5} - 1) \\ &= \frac{1}{16}(2\sqrt{3} - 2\sqrt{15} + \sqrt{40 + 8\sqrt{5}}) \end{aligned} \quad (1)$$

and

$$\begin{aligned} \cos\left(\frac{\pi}{15}\right) &= \cos\left(\frac{\pi}{6} - \frac{\pi}{10}\right) \\ &= \cos\left(\frac{\pi}{6}\right) \cos\left(\frac{\pi}{10}\right) + \sin\left(\frac{\pi}{6}\right) \sin\left(\frac{\pi}{10}\right) \\ &= \frac{\sqrt{3}}{2} \sqrt{\frac{1}{8}(5 + \sqrt{5})} + \frac{1}{2} \frac{1}{4}(\sqrt{5} - 1) \\ &= \frac{1}{8}(\sqrt{30 + 6\sqrt{5}} + \sqrt{5} - 1). \end{aligned} \quad (2)$$

Summarizing,

$$\begin{aligned} \sin\left(\frac{\pi}{15}\right) &= \frac{1}{16}(2\sqrt{3} - 2\sqrt{15} + \sqrt{40 + 8\sqrt{5}}) \\ &\approx 0.20791 \end{aligned} \quad (3)$$

$$\begin{aligned} \sin\left(\frac{2\pi}{15}\right) &= \frac{1}{8}(\sqrt{3} + \sqrt{15} - \sqrt{10 - 2\sqrt{5}}) \\ &\approx 0.40673 \end{aligned} \quad (4)$$

$$\cos\left(\frac{\pi}{15}\right) = \frac{1}{8}(\sqrt{30 + 6\sqrt{5}} + \sqrt{5} - 1) \approx 0.97814 \quad (5)$$

$$\cos\left(\frac{2\pi}{15}\right) = \frac{1}{8}(\sqrt{30 - 6\sqrt{5}} + 1) \approx 0.91354 \quad (6)$$

$$\begin{aligned} \tan\left(\frac{\pi}{15}\right) &= \frac{1}{2}(3\sqrt{3} - \sqrt{15} - \sqrt{50 - 22\sqrt{5}}) \\ &\approx 0.21255. \end{aligned} \quad (7)$$

#### Trigonometry Values— $\pi/16$

$$\begin{aligned} \sin\left(\frac{\pi}{16}\right) &= \sin\left(\frac{1}{2} \cdot \frac{\pi}{8}\right) \\ &= \sqrt{\frac{1}{2}\left(1 - \cos\frac{\pi}{8}\right)} = \sqrt{\frac{1}{2}\left(1 - \frac{1}{2}\sqrt{2 + \sqrt{2}}\right)} \\ &= \sqrt{\frac{1}{2} - \frac{1}{4}\sqrt{2 + \sqrt{2}}} = \frac{1}{2}\sqrt{2 - \sqrt{2 + \sqrt{2}}} \end{aligned} \quad (1)$$

$$\begin{aligned} \cos\left(\frac{\pi}{16}\right) &= \cos\left(\frac{1}{2} \cdot \frac{\pi}{8}\right) \\ &= \sqrt{\frac{1}{2}\left(1 + \cos\frac{\pi}{8}\right)} = \sqrt{\frac{1}{2}\left(1 + \frac{1}{2}\sqrt{2 + \sqrt{2}}\right)} \\ &= \sqrt{\frac{1}{2} + \frac{1}{4}\sqrt{2 + \sqrt{2}}} = \frac{1}{2}\sqrt{2 + \sqrt{2 + \sqrt{2}}} \end{aligned} \quad (2)$$

$$\begin{aligned} \tan\left(\frac{\pi}{16}\right) &= \sqrt{\frac{2 - \sqrt{2 + \sqrt{2}}}{2 + \sqrt{2 + \sqrt{2}}}} \\ &= \sqrt{4 + 2\sqrt{2}} - \sqrt{2} - 1. \end{aligned} \quad (3)$$

Summarizing,

$$\sin\left(\frac{\pi}{16}\right) = \frac{1}{2}\sqrt{2 - \sqrt{2 + \sqrt{2}}} \approx 0.19509 \quad (4)$$

$$\sin\left(\frac{3\pi}{16}\right) = \frac{1}{2}\sqrt{2 - \sqrt{2 - \sqrt{2}}} \approx 0.55557 \quad (5)$$

$$\cos\left(\frac{\pi}{16}\right) = \frac{1}{2}\sqrt{2 + \sqrt{2 + \sqrt{2}}} \approx 0.98079 \quad (6)$$

$$\cos\left(\frac{3\pi}{16}\right) = \frac{1}{2}\sqrt{2 + \sqrt{2 - \sqrt{2}}} \approx 0.83147 \quad (7)$$

$$\tan\left(\frac{\pi}{16}\right) = \sqrt{4 + 2\sqrt{2}} - \sqrt{2} - 1 \approx 0.19891. \quad (8)$$

### Trigonometry Values— $\pi/17$

Rather surprisingly, trigonometric functions of  $n\pi/17$  for  $n$  an integer can be expressed in terms of sums, products, and finite root extractions because 17 is a FERMAT PRIME. This makes the HEPTADECAGON a CONSTRUCTIBLE, as first proved by Gauss. Although Gauss did not actually explicitly provide a construction, he did derive the trigonometric formulas below using a series of intermediate variables from which the final expressions were then built up.

Let

$$\epsilon \equiv \sqrt{17 + \sqrt{17}}$$

$$\epsilon^* \equiv \sqrt{17 - \sqrt{17}}$$

$$\alpha \equiv \sqrt{\sqrt{34} + 6\sqrt{17} + (\sqrt{34} - \sqrt{2})\epsilon^* - 8\sqrt{2}\epsilon}$$

$$\beta \equiv 2\sqrt{17 + 3\sqrt{17} - 2\sqrt{2}\epsilon - \sqrt{2}\epsilon^*}.$$

Then

$$\begin{aligned} \sin\left(\frac{\pi}{17}\right) &= \frac{1}{8}[34 - 2\sqrt{17} - 2\sqrt{2}\epsilon^* \\ &\quad - 2\sqrt{68 + 12\sqrt{17} + 2\sqrt{2}(\sqrt{17} - 1)\epsilon^* - 16\sqrt{2}\epsilon}]^{1/2} \\ &\approx 0.18375 \end{aligned}$$

$$\begin{aligned} \cos\left(\frac{\pi}{17}\right) &= \frac{1}{8}[30 + 2\sqrt{17} + 2\sqrt{2}\epsilon^* \\ &\quad + 2\sqrt{68 + 12\sqrt{17} + 2\sqrt{2}(\sqrt{17} - 1)\epsilon^* - 16\sqrt{2}\epsilon}]^{1/2} \\ &\approx 0.98297 \end{aligned}$$

$$\begin{aligned} \sin\left(\frac{2\pi}{17}\right) &= \frac{1}{16}[136 - 8\sqrt{17} + 4\sqrt{2}(1 - \sqrt{17})\epsilon^* + 16\sqrt{2}\epsilon \\ &\quad + 2(\sqrt{2} - \sqrt{34} - 2\epsilon^*)\sqrt{34 + 6\sqrt{17} + (\sqrt{34} - \sqrt{2})\epsilon^* - 8\sqrt{2}\epsilon}]^{1/2} \\ &\approx 0.36124 \end{aligned}$$

$$\begin{aligned} \cos\left(\frac{2\pi}{17}\right) &= \frac{1}{16}[-1 + \sqrt{17} + \sqrt{2}\epsilon^* \\ &\quad + \sqrt{68 + 12\sqrt{17} - 2\sqrt{2}(1 - \sqrt{17})\epsilon^* - 16\sqrt{2}\epsilon}] \\ &\approx 0.093247 \end{aligned}$$

$$\begin{aligned} \sin\left(\frac{4\pi}{17}\right) &= \frac{1}{128}(-\sqrt{2} + \sqrt{34} + 2\epsilon^* + 2\alpha) \\ &\quad \times \sqrt{68 - 4\sqrt{17} - 2(\sqrt{34} - \sqrt{2})\epsilon^* + 8\sqrt{2}\epsilon + \alpha(\sqrt{2} - \sqrt{34} - 2\epsilon^*)} \\ &\approx 0.0.67370 \end{aligned}$$

$$\begin{aligned} \sin\left(\frac{8\pi}{17}\right) &= \frac{1}{16}[136 - 8\sqrt{17} + 8\sqrt{2}\epsilon - 2(\sqrt{34} - 3\sqrt{2})\epsilon^* \\ &\quad - 2\beta(1 - \sqrt{17} - \sqrt{2}\epsilon^*)]^{1/2} \\ &\approx 0.99573 \end{aligned}$$

$$\begin{aligned} \cos\left(\frac{8\pi}{17}\right) &= \frac{1}{16}(-1 + \sqrt{17} + \sqrt{2}\epsilon^* \\ &\quad - 2\sqrt{17 + 3\sqrt{17} - \sqrt{2}\epsilon^* - 2\sqrt{2}\epsilon}). \\ &\approx 0.09227 \end{aligned}$$

There are some interesting analytic formulas involving the trigonometric functions of  $n\pi/17$ . Define

$$P(x) \equiv (x - 1)(x - 2)(x^2 + 1)$$

$$g_1(x) \equiv \frac{2 + \sqrt{P(x)}}{1 - x}$$

$$g_4(x) \equiv \frac{2 - \sqrt{P(x)}}{1 - x}$$

$$f_i(x) \equiv \frac{1}{4}[g_i(x) - 1]$$

$$a \equiv \frac{1}{4}\tan^{-1} 4,$$

where  $i = 1$  or  $4$ . Then

$$f_1(\tan a) = \cos\left(\frac{2\pi}{17}\right)$$

$$f_4(\tan a) = \cos\left(\frac{8\pi}{17}\right).$$

### Trigonometry Values— $\pi/18$

The exact values of  $\cos(\pi/18)$  and  $\sin(\pi/18)$  are given by infinite NESTED RADICALS.

$$\begin{aligned} \sin\left(\frac{\pi}{18}\right) &= \frac{1}{2}\sqrt{2 - \sqrt{2 + \sqrt{2 + \sqrt{2} - \dots}}} \\ &\approx 0.17365, \end{aligned}$$

where the sequence of signs  $+$ ,  $+$ ,  $-$  repeats with period 3, and

$$\begin{aligned} \cos\left(\frac{\pi}{18}\right) &= \frac{1}{6}\sqrt{3} \left( \sqrt{8 - \sqrt{8 - \sqrt{8 + \sqrt{8 - \dots} + 1}}} \right) \\ &\approx 0.98481, \end{aligned}$$

where the sequence of signs  $-$ ,  $-$ ,  $+$  repeats with period 3.

**Trigonometry Values— $\pi/20$** 

$$\begin{aligned}\sin\left(\frac{\pi}{20}\right) &= \sin\left(\frac{1}{2}\frac{\pi}{10}\right) = \sqrt{\frac{1}{2}\left(1 - \cos\frac{\pi}{10}\right)} \\ &= \frac{1}{4}\sqrt{8 - 2\sqrt{10 + 2\sqrt{5}}} \\ &\approx 0.15643\dots\end{aligned}\quad (1)$$

$$\begin{aligned}\cos\left(\frac{\pi}{20}\right) &= \cos\left(\frac{1}{2}\frac{\pi}{10}\right) = \sqrt{\frac{1}{2}\left(1 + \cos\frac{\pi}{10}\right)} \\ &= \frac{1}{4}\sqrt{8 + 2\sqrt{10 + 2\sqrt{5}}} \\ &\approx 0.98768\dots\end{aligned}\quad (2)$$

$$\begin{aligned}\tan\left(\frac{\pi}{20}\right) &= 1 + \sqrt{5} - \sqrt{5 + 2\sqrt{5}} \\ &\approx 0.15838.\end{aligned}\quad (3)$$

An interesting near-identity is given by

$$\frac{1}{4}\left[\cos\left(\frac{1}{10}\right) + \cosh\left(\frac{1}{10}\right) + 2\cos\left(\frac{1}{20}\sqrt{2}\right)\cosh\left(\frac{1}{20}\sqrt{2}\right)\right] \approx 1. \quad (4)$$

In fact, the left-hand side is approximately equal to  $1 + 2.480 \times 10^{-13}$ .

**Trigonometry Values—0**

By the definition of the trigonometric functions,

$$\begin{aligned}\sin 0 &= 0 \\ \cos 0 &= 1 \\ \tan 0 &= 0 \\ \csc 0 &= \infty \\ \sec 0 &= 1 \\ \cot 0 &= \infty.\end{aligned}$$

**Trihedron**

The TRIPLE of unit ORTHOGONAL VECTORS **T**, **N**, and **B** (TANGENT VECTOR, NORMAL VECTOR, and BINORMAL VECTOR).

see also BINORMAL VECTOR, NORMAL VECTOR, TANGENT VECTOR

**Trilinear Coordinates**

Given a TRIANGLE  $\triangle ABC$ , the trilinear coordinates of a point  $P$  with respect to  $\triangle ABC$  are an ordered TRIPLE of numbers, each of which is PROPORTIONAL to the directed distance from  $P$  to one of the side lines. Trilinear coordinates are denoted  $\alpha : \beta : \gamma$  or  $(\alpha, \beta, \gamma)$  and also are known as BARYCENTRIC COORDINATES, HOMOGENEOUS COORDINATES, or "trilinears."

In trilinear coordinates, the three VERTICES  $A$ ,  $B$ , and  $C$  are given by  $1 : 0 : 0$ ,  $0 : 1 : 0$ , and  $0 : 0 : 1$ . Let the point  $P$  in the above diagram have trilinear coordinates  $\alpha : \beta : \gamma$  and lie at distances  $a'$ ,  $b'$ , and  $c'$  from the sides  $BC$ ,  $AC$ , and  $AB$ , respectively. Then the distances  $a' = k\alpha$ ,  $b' = k\beta$ , and  $c' = k\gamma$  can be found by writing  $\Delta_a$  for the AREA of  $\triangle BPC$ , and similarly for  $\Delta_b$  and  $\Delta_c$ . We then have

$$\begin{aligned}\Delta &= \Delta_a + \Delta_b + \Delta_c = \frac{1}{2}aa' + \frac{1}{2}bb' + \frac{1}{2}cc' \\ &= \frac{1}{2}(ak\alpha + bk\beta + ck\gamma) = \frac{1}{2}k(a\alpha + b\beta + c\gamma).\end{aligned}\quad (1)$$

so

$$k \equiv \frac{2\Delta}{a\alpha + b\beta + c\gamma}, \quad (2)$$

where  $\Delta$  is the AREA of  $\triangle ABC$  and  $a$ ,  $b$ , and  $c$  are the lengths of its sides. When the values of the coordinates are taken as the actual lengths (i.e., the trilinears are chosen so that  $k = 1$ ), the coordinates are known as EXACT TRILINEAR COORDINATES.

Trilinear coordinates are unchanged when each is multiplied by any constant  $\mu$ , so

$$t_1 : t_2 : t_3 = \mu t_1 : \mu t_2 : \mu t_3. \quad (3)$$

When normalized so that

$$t_1 + t_2 + t_3 = 1, \quad (4)$$

trilinear coordinates are called AREAL COORDINATES. The trilinear coordinates of the line

$$ux + vy + wz = 0 \quad (5)$$

are

$$u : v : w = ad_A : bd_B : cd_C, \quad (6)$$

where  $d_i$  is the POINT-LINE DISTANCE from VERTEX  $A$  to the LINE.

Trilinear coordinates for some common POINTS are summarized in the following table, where  $A$ ,  $B$ , and  $C$  are the angles at the corresponding vertices and  $a$ ,  $b$ , and  $c$  are the opposite side lengths.

Point	Triangle Center Function
centroid $M$	$\csc A, 1/a$
circumcenter $O$	$\cos A$
de Longchamps point	$\cos A - \cos B \cos C$
equal detour point	$\sec(\frac{1}{2}A) \cos(\frac{1}{2}B) \cos(\frac{1}{2}C) + 1$
Feuerbach point $F$	$1 - \cos(B - C)$
incenter $I$	1
isoperimetric point	$\sec(\frac{1}{2}A) \cos(\frac{1}{2}B) \cos(\frac{1}{2}C) - 1$
Lemoine point	$a$
nine-point center $N$	$\cos(B - C)$
orthocenter $H$	$\cos B \cos C$
vertex $A$	$1 : 0 : 0$
vertex $B$	$0 : 1 : 0$
vertex $C$	$0 : 0 : 1$

To convert trilinear coordinates to a vector position for a given triangle specified by the  $x$ - and  $y$ -coordinates of its axes, pick two UNIT VECTORS along the sides. For instance, pick

$$\hat{\mathbf{a}} = \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} \quad (7)$$

$$\hat{\mathbf{c}} = \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}, \quad (8)$$

where these are the UNIT VECTORS  $BC$  and  $AB$ . Assume the TRIANGLE has been labeled such that  $A = \mathbf{x}_1$  is the lower rightmost VERTEX and  $C = \mathbf{x}_2$ . Then the VECTORS obtained by traveling  $l_a$  and  $l_c$  along the sides and then inward PERPENDICULAR to them must meet

$$\begin{aligned} \begin{bmatrix} x_1 \\ y_1 \end{bmatrix} + l_c \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} - k\gamma \begin{bmatrix} c_2 \\ -c_1 \end{bmatrix} \\ = \begin{bmatrix} x_2 \\ y_2 \end{bmatrix} + l_a \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} - k\alpha \begin{bmatrix} a_2 \\ -a_1 \end{bmatrix}. \end{aligned} \quad (9)$$

Solving the two equations

$$x_1 + l_c c_1 - k\gamma c_2 = x_2 l_a a_1 - k\alpha a_2 \quad (10)$$

$$y_1 + l_c c_2 + k\gamma c_1 = y_2 l_a a_2 + k\alpha a_1, \quad (11)$$

gives

$$l_c = \frac{k\alpha(a_1 c_1 + a_2 c_2) - \gamma k(c_1^2 + c_2^2) + c_2(x_1 - x_2) + c_1(y_2 - y_1)}{a_1 c_2 - a_2 c_1} \quad (12)$$

$$l_a = \frac{k\alpha(a_1^2 + a_2^2) - \gamma k(a_1 c_1 + a_2 c_2) + a_2(x_1 - x_2) + a_1(y_2 - y_1)}{a_1 c_2 - a_2 c_1}. \quad (13)$$

But  $\hat{\mathbf{a}}$  and  $\hat{\mathbf{c}}$  are UNIT VECTORS, so

$$l_c = \frac{k\alpha(a_1 c_1 + a_2 c_2) - \gamma k + c_2(x_1 - x_2) + c_1(y_2 - y_1)}{a_1 c_2 - a_2 c_1} \quad (14)$$

$$l_a = \frac{k\alpha - \gamma k(a_1 c_1 + a_2 c_2) + a_2(x_1 - x_2) + a_1(y_2 - y_1)}{a_1 c_2 - a_2 c_1}. \quad (15)$$

And the VECTOR coordinates of the point  $\alpha : \beta : \gamma$  are then

$$\mathbf{x} = \mathbf{x}_1 + l_c \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} - k\gamma \begin{bmatrix} c_2 \\ -c_1 \end{bmatrix}. \quad (16)$$

#### Trimagic Square

If replacing each number by its square or cube in a MAGIC SQUARE produces another MAGIC SQUARE, the square is said to be a trimagic square. Trimagic squares of order 32, 64, 81, and 128 are known. Tarry gave a method for constructing a trimagic square of order 128, Cazalas a method for trimagic squares of orders 64 and 81, and R. V. Heath a method for constructing an order 64 trimagic square which is different from Cazalas's (Kraitchik 1942).

Trimagic squares are also called TREBLY MAGIC SQUARES, and are 3-MULTIMAGIC SQUARES.

see also BIMAGIC SQUARE, MAGIC SQUARE, MULTIMAGIC SQUARE

#### Trimean

The trimean is defined to be

$$TM \equiv \frac{1}{4}(H_1 + 2M + H_2),$$

where  $H_i$  are the HINGES and  $M$  is the MEDIAN. Press *et al.* (1992) call this TUKEY’S TRIMEAN. It is an  $L$ -ESTIMATE.

see also HINGE,  $L$ -ESTIMATE, MEAN, MEDIAN (STATISTICS)

#### Trinoid

A MINIMAL SURFACE discovered by L. P. M. Jorge and W. Meeks III in 1983 with ENNEPER-WEIERSTRASS PARAMETERIZATION

$$f = \frac{1}{(\zeta^3 - 1)^2} \quad (1)$$

$$g = \zeta^2 \quad (2)$$

(Dickson 1990). Explicitly, it is given by

$$x = \Re \left[ \frac{re^{i\theta}}{3(1 + re^{i\theta} + r^2e^{2i\theta})} - \frac{4\ln(re^{i\theta} - 1)}{9} + \frac{2\ln(1 + re^{i\theta} + r^2e^{2i\theta})}{9} \right] \quad (3)$$

$$y = -\frac{1}{9}\Im \left[ \frac{-3re^{i\theta}(1 + re^{i\theta})}{r^3e^{3i\theta} - 1} + \frac{4\sqrt{3}(r^3e^{3i\theta} - 1)\tan^{-1}\left(\frac{1+2re^{i\theta}}{\sqrt{3}}\right)}{r^3e^{3i\theta} - 1} \right] \quad (4)$$

$$z = \Re \left[ -\frac{2}{3} - \frac{2}{3(r^3e^{3i\theta} - 1)} \right], \quad (5)$$

for  $\theta \in [0, 2\pi)$  and  $r \in [0, 4]$ .

see also MINIMAL SURFACE

#### Trinomial

A POLYNOMIAL with three terms.

see also BINOMIAL, MONOMIAL, POLYNOMIAL

#### Trinomial Identity

$$(x^2 + axy + by^2)(t^2 + atu + bu^2) = r^2 + ars + bs^2, \quad (1)$$

where

$$r = xt - byu \quad (2)$$

$$s = yt + xu + ayu. \quad (3)$$

#### Trinomial Triangle

The NUMBER TRIANGLE obtained by starting with a row containing a single “1” and the next row containing three 1s and then letting subsequent row elements be

computed by summing the elements above to the left, directly above, and above to the right:

				1				
			1	1	1			
		1	2	3	2	1		
	1	3	6	7	6	3	1	
1	4	10	16	19	16	10	4	1

(Sloane's A027907). The  $n$ th row can also be obtained by expanding  $(1 + x + x^2)^n$  and taking coefficients:

$$\begin{aligned}(1 + x + x^2)^0 &= 1 \\ (1 + x + x^2)^1 &= 1 + x + x^2 \\ (1 + x + x^2)^2 &= 1 + 2x + 3x^2 + 2x^3 + x^4\end{aligned}$$

and so on.

see also PASCAL'S TRIANGLE

#### References

#### Triple

A group of three elements, also called a TRIAD.

see also AMICABLE TRIPLE, MONAD, PAIR, PYTHAGOREAN TRIPLE, QUADRUPLET, QUINTUPLET, TETRAD, TRIAD, TWINS

#### Triple-Free Set

A SET of POSITIVE integers is called weakly triple-free if, for any integer  $x$ , the SET  $\{x, 2x, 3x\} \not\subset S$ . It is called strongly triple-free if  $x \in S$  IMPLIES  $2x \notin S$  and  $3x \notin S$ . Define

$$\begin{aligned}p(n) &= \max\{|S| : S \subset \{1, 2, \dots, n\} \\ &\quad \text{is weakly triple-free}\} \\ q(n) &= \max\{|S| : S \subset \{1, 2, \dots, n\} \\ &\quad \text{is strongly triple-free}\},\end{aligned}$$

where  $|S|$  denotes the CARDINALITY of  $S$ , then

$$\lim_{n \rightarrow \infty} \frac{p(n)}{n} \geq \frac{4}{5}$$

and

$$\lim_{n \rightarrow \infty} \frac{q(n)}{n} = 0.6134752692 \dots$$

(Finch).

**Trisection**

Angle trisection is the division of an *arbitrary* ANGLE into three equal ANGLES. It was one of the three GEOMETRIC PROBLEMS OF ANTIQUITY for which solutions using only COMPASS and STRAIGHTEDGE were sought. The problem was algebraically proved impossible by Wantzel (1836).

Although trisection is not possible for a general ANGLE using a Greek construction, there are some specific angles, such as  $\pi/2$  and  $\pi$  radians ( $90^\circ$  and  $180^\circ$ , respectively), which *can* be trisected. Furthermore, some ANGLES are geometrically trisectable, but cannot be constructed in the first place, such as  $3\pi/7$  (Honsberger 1991). In addition, trisection of an arbitrary angle *can* be accomplished using a *marked* RULER (a NEUSIS CONSTRUCTION) as illustrated below (Courant and Robbins 1996).

An ANGLE can also be divided into three (or any WHOLE NUMBER) of equal parts using the QUADRATRIX OF HIPPIAS or TRISECTRIX.

**Triskaidekaphobia**

The number 13 is traditionally associated with bad luck. This superstition leads some people to fear or avoid anything involving this number, a condition known as triskaidekaphobia. Triskaidekaphobia leads to interesting practices such as the numbering of floors as 1, 2, ..., 11, 12, 14, 15, ..., *omitting the number 13*, in many high-rise hotels.

see also 13, BAKER'S DOZEN, FRIDAY THE THIRTEENTH, TRISKAIDEKAPHOBIA

**Tritangent**

The tritangent of a CUBIC SURFACE is a PLANE which intersects the surface in three mutually intersecting lines. Each intersection of two lines is then a tangent point of the surface.

see also CUBIC SURFACE

- Hunt, B. "Algebraic Surfaces." <http://www.mathematik.uni-kl.de/~wwagag/Galerie.html>.

**Tritangent Triangle**

see EXCENTRAL TRIANGLE

**Trivial**

According to the Nobel Prize-winning physicist Richard Feynman (1985), mathematicians designate any THEOREM as “trivial” once a proof has been obtained—no matter how difficult the theorem was to prove in the first place. There are therefore exactly two types of true mathematical propositions: trivial ones, and those which have not yet been proven.

see also PROOF, THEOREM

**References**

Feynman, R. P. and Leighton, R. *Surely You're Joking, Mr. Feynman!* New York: Bantam Books, 1985.

**Trivialization**

In the definition of a FIBER BUNDLE  $f : E \rightarrow B$ , the homeomorphisms  $g_U : f^{-1}(U) \rightarrow U \times F$  that commute with projection are called local trivializations for the FIBER BUNDLE  $f$ .

see also FIBER BUNDLE

**Trochoid**

The curve described by a point at a distance  $b$  from the center of a rolling CIRCLE of RADIUS  $a$ .

$$x = a\phi - b\sin\phi$$

$$y = a - b\cos\phi.$$

If  $b < a$ , the curve is a CURTATE CYCLOID. If  $b = a$ , the curve is a CYCLOID. If  $b > a$ , the curve is a PROLATE CYCLOID.

**Tromino**

see TRIOMINO

**True**

A statement which is rigorously known to be correct. A statement which is not true is called FALSE, although certain statements can be proved to be rigorously UNDECIDABLE within the confines of a given set of assumptions and definitions. Regular two-valued LOGIC allows statements to be only true or FALSE, but FUZZY LOGIC treats “truth” as a continuum which can have any value between 0 and 1.

see also ALETHIC, FALSE, FUZZY LOGIC, LOGIC, TRUTH TABLE, UNDECIDABLE

**Truncate**

To truncate a REAL NUMBER is to remove its nonintegral part. Truncation of a number  $x$  therefore corresponds to taking the FLOOR FUNCTION  $|x|$ .

see also CEILING FUNCTION, FLOOR FUNCTION, NINT, ROUND

**Truncated Cone**

see CONICAL FRUSTUM

**Truncated Cube**

An ARCHIMEDEAN SOLID whose DUAL POLYHEDRON is the TRIAKIS OCTAHEDRON. It has SCHLÄFLI SYMBOL  $t\{4,3\}$ . It is also UNIFORM POLYHEDRON  $U_9$  and has WYTHOFF SYMBOL  $23|4$ . Its faces are  $8\{3\}+6\{8\}$ . The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for  $a = 1$  are

$$r = \frac{1}{17}(5 + 2\sqrt{2})\sqrt{7 + 4\sqrt{2}} \approx 1.63828$$

$$\rho = \frac{1}{2}(2 + \sqrt{2}) \approx 1.70711$$

$$R = \frac{1}{2}\sqrt{7 + 4\sqrt{2}} \approx 1.77882.$$

## Truncated Icosahedron

An ARCHIMEDEAN SOLID used in the construction of SOCCER BALLS. Its DUAL POLYHEDRON is the PENTAKIS DODECAHEDRON. It has SCHLÄFLI SYMBOL  $t\{3,5\}$ . It is also UNIFORM POLYHEDRON  $U_{25}$  and has WYTHOFF SYMBOL  $2\ 5\ |\ 3$ . Its faces are  $20\{6\} + 12\{5\}$ . The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for  $a = 1$  are

$$r = \frac{9}{872}(21 + \sqrt{5})\sqrt{58 + 18\sqrt{5}} \approx 2.37713$$

$$\rho = \frac{3}{4}(1 + \sqrt{5}) \approx 2.42705$$

$$R = \frac{1}{4}\sqrt{58 + 18\sqrt{5}} \approx 2.47802.$$

## Truncated Icosidodecahedron

see GREAT RHOMBICOSIDODECAHEDRON (ARCHIMEDEAN)

## Truncated Octahedral Number

A FIGURATE NUMBER which is constructed as an OCTAHEDRAL NUMBER with a SQUARE PYRAMID removed from each of the six VERTICES,

$$TO_n = O_{3n-2} - 6P_{n-1} = \frac{1}{3}(3n-2)[2(3n-2)^2 + 1],$$

where  $O_n$  is an OCTAHEDRAL NUMBER and  $P_n$  is a PYRAMIDAL NUMBER. The first few are 1, 38, 201, 586, ... (Sloane's A005910). The GENERATING FUNCTION for the truncated octahedral numbers is

$$\frac{x(6x^3 + 55x^2 + 34x + 1)}{(x-1)^4} = x + 38x^2 + 201x^3 + \dots$$

see also OCTAHEDRAL NUMBER

### References

Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, p. 52, 1996.  
Sloane, N. J. A. Sequence A005910/M5266 in "An On-Line Version of the Encyclopedia of Integer Sequences."

### Truncated Octahedron

An ARCHIMEDEAN SOLID, also known as the MECON, whose DUAL POLYHEDRON is the TETRAKIS HEXAHEDRON. It is also UNIFORM POLYHEDRON  $U_8$  and has SCHLÄFLI SYMBOL  $t\{3,4\}$  and WYTHOFF SYMBOL  $24|3$ . The faces of the truncated octahedron are  $8\{6\}+6\{4\}$ . The truncated octahedron has the  $O_h$  OCTAHEDRAL GROUP of symmetries.

The solid can be formed from an OCTAHEDRON via TRUNCATION by removing six SQUARE PYRAMIDS, each with edge slant height  $a = s/3$  and height  $h$ , where  $s$  is the side length of the original OCTAHEDRON. From the above diagram, the height and base area of the SQUARE PYRAMID are

$$\begin{aligned} h &= \sqrt{a^2 - d^2} = \frac{1}{2}\sqrt{2}a \\ A_b &= a^2. \end{aligned} \quad (1)$$

The VOLUME of the truncated octahedron is then given by the VOLUME of the OCTAHEDRON

$$V_{\text{octahedron}} = \frac{1}{3}\sqrt{2}s^3 = 9\sqrt{2}a^3 \quad (3)$$

minus six times the volume of the SQUARE PYRAMID,

$$V = V_{\text{octahedron}} - 6\left(\frac{1}{3}A_b h\right) = (9\sqrt{2} - \sqrt{2})a^3 = 8\sqrt{2}a^3. \quad (4)$$

The truncated octahedron is a SPACE-FILLING POLYHEDRON. The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for  $a = 1$  are

$$r = \frac{9}{20}\sqrt{10} \approx 1.42302 \quad (5)$$

$$\rho = \frac{3}{2} = 1.5 \quad (6)$$

$$R = \frac{1}{2}\sqrt{10} \approx 1.58114. \quad (7)$$

see also OCTAHEDRON, SQUARE PYRAMID, TRUNCATION

### References

Coxeter, H. S. M. *Regular Polytopes*, 3rd ed. New York: Dover, pp. 29–30 and 257, 1973.

### Truncated Polyhedron

A polyhedron with truncated faces, given by the SCHLÄFLI SYMBOL  $t\left\{\frac{p}{q}\right\}$ .

see also RHOMBIC POLYHEDRON, SNUB POLYHEDRON

### Truncated Pyramid

see PYRAMIDAL FRUSTUM

### Truncated Square Pyramid

The truncated square pyramid is a special case of a PYRAMIDAL FRUSTUM for a SQUARE PYRAMID. Let the base and top side lengths of the truncated pyramid be  $a$  and  $b$ , and let the height be  $h$ . Then the VOLUME of the solid is

$$V = \frac{1}{3}(a^2 + ab + b^2)h.$$

This FORMULA was known to the Egyptians ca. 1850 BC. The Egyptians cannot have proved it without calculus, however, since Dehn showed in 1900 that no proof of this equation exists which does not rely on the concept of continuity (and therefore some form of INTEGRATION).

see also FRUSTUM, PYRAMID, PYRAMIDAL FRUSTUM, SQUARE PYRAMID

### Truncated Tetrahedral Number

A FIGURATE NUMBER constructed by taking the  $(3n - 2)$ th TETRAHEDRAL NUMBER and removing the  $(n - 1)$ th TETRAHEDRAL NUMBER from each of the four corners,

$$Ttct_n \equiv Tc_{3n-3} - 4Tc_{n-1} = \frac{1}{6}n(23n^2 - 27n + 10).$$

The first few are 1, 16, 68, 180, 375, ... (Sloane's A005906). The GENERATING FUNCTION for the truncated tetrahedral numbers is

$$\frac{x(10x^2 + 12x + 1)}{(x - 1)^4} = x + 16x^2 + 89x^3 + 180x^4 + \dots$$

### References

Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, pp. 46–47, 1996.

## Truncated Tetrahedron

An ARCHIMEDEAN SOLID whose dual is the TRIAKIS TETRAHEDRON. It has SCHLÄFLI SYMBOL  $t\{3,3\}$ . It is also UNIFORM POLYHEDRON  $U_2$  and has WYTHOFF SYMBOL  $23|3$ . Its faces are  $4\{3\} + 4\{6\}$ . The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for a truncated tetrahedron with  $a = 1$  are

$$r = \frac{9}{44}\sqrt{22} \approx 0.95940$$

$$\rho = \frac{3}{4}\sqrt{2} \approx 1.06066$$

$$R = \frac{1}{4}\sqrt{22} \approx 1.17260.$$

## Truncation

The removal of portions of SOLIDS falling outside a set of symmetrically placed planes. The five PLATONIC SOLIDS belong to one of the following three truncation series (which, in the first two cases, carry the solid to its DUAL POLYHEDRON).

see also STELLATION, TRUNCATED CUBE, TRUNCATED DODECAHEDRON, TRUNCATED ICOSAHEDRON, TRUNCATED OCTAHEDRON, TRUNCATED TETRAHEDRON, VERTEX FIGURE

## Truth Table

A truth table is a 2-D array with  $n + 1$  columns. The first  $n$  columns correspond to the possible values of  $n$  inputs, and the last column to the operation being performed. The rows list all possible combinations of inputs

together with the corresponding outputs. For example, the following truth table shows the result of the binary AND operator acting on two inputs  $A$  and  $B$ , each of which may be true or false.

$A$	$B$	$A \wedge B$
F	F	F
F	T	F
T	F	F
T	T	T

see also AND, MULTIPLICATION TABLE, OR, XOR

## Tschebyshev

An alternative spelling of the name "Chebyshev."

## Tschirnhausen Cubic

The Tschirnhausen cubic is a plane curve given by

$$a = r \cos^3 \left( \frac{1}{3}\theta \right),$$

and is also known as CATALAN'S TRISECTRIX and L'HOSPITAL'S CUBIC. The name Tschirnhaus's cubic is given in R. C. Archibald's 1900 paper attempting to classify curves (MacTutor Archive). Tschirnhaus's cubic is the NEGATIVE PEDAL CURVE of a PARABOLA with respect to the FOCUS.

## Tschirnhausen Cubic Caustic

The CAUSTIC of the TSCHIRNHAUSEN CUBIC taking the RADIANT POINT as the pole is NEILE'S PARABOLA.

**Tschirnhausen Cubic Pedal Curve**

The PEDAL CURVE to the TSCHIRNHAUSEN CUBIC for PEDAL POINT at the origin is the PARABOLA

$$\begin{aligned}x &= 1 - t^2 \\ y &= 2t.\end{aligned}$$

see also PARABOLA, PEDAL CURVE, PEDAL POINT, TSCHIRNHAUSEN CUBIC

**Tschirnhausen Transformation**

A transformation of a POLYNOMIAL equation  $f(x) = 0$  which is of the form  $y = g(x)/h(x)$  where  $g$  and  $h$  are POLYNOMIALS and  $h(x)$  does not vanish at a root of  $f(x) = 0$ . The CUBIC EQUATION is a special case of such a transformation. Tschirnhaus (1683) showed that a POLYNOMIAL of degree  $n > 2$  can be reduced to a form in which the  $x^{n-1}$  and  $x^{n-2}$  terms have 0 COEFFICIENTS. In 1786, E. S. Bring showed that a general QUINTIC EQUATION can be reduced to the form

$$x^5 + px + q = 0.$$

In 1834, G. B. Jerrard showed that a Tschirnhaus transformation can be used to eliminate the  $x^{n-1}$ ,  $x^{n-2}$ , and  $x^{n-3}$  terms for a general POLYNOMIAL equation of degree  $n > 3$ .

**Tubular Neighborhood**

The tubular embedding of a SUBMANIFOLD  $M^m \subset N^n$  is an EMBEDDING  $t: M \times \mathbb{B}^{n-m} \rightarrow N$  such that  $t(x, 0) = x$  whenever  $x \in M$ , where  $\mathbb{B}^{n-m}$  is the unit BALL in  $\mathbb{R}^{n-m}$  centered at 0. The tubular neighborhood is also called the PRODUCT NEIGHBORHOOD.

see also BALL, EMBEDDING, PRODUCT NEIGHBORHOOD

**Tucker Circles**

Let three equal lines  $P_1Q_1$ ,  $P_2Q_2$ , and  $P_3Q_3$  be drawn ANTIPARALLEL to the sides of a triangle so that two (say  $P_2Q_2$  and  $P_3Q_3$ ) are on the same side of the third line as  $A_2P_2Q_3A_3$ . Then  $P_2Q_3P_3Q_2$  is an isosceles TRAPEZOID, i.e.,  $P_3Q_2$ ,  $P_1Q_3$ , and  $P_2Q_1$  are parallel to the respective sides. The MIDPOINTS  $C_1$ ,  $C_2$ , and  $C_3$  of the antiparallels are on the respective symmedians and divide them proportionally.

If  $T$  divides  $KO$  in the same ratio,  $TC_1$ ,  $TC_2$ ,  $TC_3$  are parallel to the radii  $OA_1$ ,  $OA_2$ , and  $OA_3$  and equal. Since the antiparallels are perpendicular to the symmedians, they are equal chords of a circle with center  $T$  which passes through the six given points. This circle is called the Tucker circle.

If

$$c \equiv \frac{\overline{KC_1}}{\overline{KA_1}} = \frac{\overline{KC_2}}{\overline{KA_2}} = \frac{\overline{KC_3}}{\overline{KA_3}} = \frac{\overline{KT}}{\overline{KO}},$$

then the radius of the Tucker circle is

$$R\sqrt{c^2 + (1 - c)^2 \tan \omega},$$

where  $\omega$  is the BROCARD ANGLE.

The COSINE CIRCLE, LEMOINE CIRCLE, and TAYLOR CIRCLE are Tucker circles.

**Tukey's Biweight**

The function

$$\psi(z) = \begin{cases} z \left(1 - \frac{z^2}{c^2}\right)^2 & \text{for } |z| < c \\ 0 & \text{for } |z| > c \end{cases}$$

sometimes used in ROBUST ESTIMATION. It has a minimum at  $z = -c/\sqrt{3}$  and a maximum at  $z = c/\sqrt{3}$ , where

$$\psi'(z) = 1 - \frac{3z^2}{c^2} = 0,$$

and an inflection point at  $z = 0$ , where

$$\psi''(z) = -\frac{6z}{c^2} = 0.$$

### Turán Graph

The  $(n, k)$ -Turán graph is the EXTREMAL GRAPH on  $n$  VERTICES which contains no  $k$ -CLIQUE. In other words, the Turán graph has the maximum possible number of EDGES of any  $n$ -vertex graph not containing a COMPLETE GRAPH  $K_k$ . TURÁN'S THEOREM gives the maximum number of edges  $t(n, k)$  for the  $(n, k)$ -Turán graph. For  $k = 3$ ,

$$t(n, 3) = \frac{1}{4}n^4,$$

so the Turán graph is given by the COMPLETE BIPARTITE GRAPHS

$$\begin{cases} K_{n/2, n/2} & n \text{ even} \\ K_{(n-1)/2, (n+1)/2} & n \text{ odd.} \end{cases}$$

### Turán's Theorem

Let  $G(V, E)$  be a GRAPH with VERTICES  $V$  and EDGES  $E$  on  $n$  VERTICES without a  $k$ -CLIQUE. Then

$$t(n, k) \leq \frac{(k-2)n^2}{2(k-1)},$$

where  $t(n, k) = |E|$  is the EDGE NUMBER. More precisely, the  $K$ -GRAPH  $K_{n_1, \dots, n_{k-1}}$  with  $|n_i - n_j| \leq 1$  for  $i \neq j$  is the unique GRAPH without a  $k$ -CLIQUE with the maximal number of EDGES  $t(n, k)$ .

### Turbine

A VECTOR FIELD on a CIRCLE in which the directions of the VECTORS are all at the same ANGLE to the CIRCLE.

see also CIRCLE, VECTOR FIELD

### Turing Machine

A theoretical computing machine which consists of an infinitely long magnetic tape on which instructions can be written and erased, a single-bit register of memory, and a processor capable of carrying out the following instructions: move the tape right, move the tape left, change the state of the register based on its current value and a value on the tape, and write or erase a value on the tape. The machine keeps processing instructions until it reaches a particular state, causing it to halt. Determining whether a Turing machine will halt for a given input and set of rules is called the HALTING PROBLEM.

**Twin Peaks**

For an INTEGER  $n \geq 2$ , let  $\text{lpf}(x)$  denote the LEAST PRIME FACTOR of  $n$ . A PAIR of INTEGERS  $(x, y)$  is called a twin peak if

1.  $x < y$ ,
2.  $\text{lpf}(x) = \text{lpf}(y)$ ,
3. For all  $z$ ,  $x < z < y$  IMPLIES  $\text{lpf}(z) < \text{lpf}(x)$ .

A broken-line graph of the least prime factor function resembles a jagged terrain of mountains. In terms of this terrain, a twin peak consists of two mountains of equal height with no mountain of equal or greater height between them. Denote the height of twin peak  $(x, y)$  by  $p = \text{lpf}(x) = \text{lpf}(y)$ . By definition of the LEAST PRIME FACTOR function,  $p$  must be PRIME.

Call the distance between two twin peaks  $(x, y)$

$$s \equiv y - x.$$

Then  $s$  must be an EVEN multiple of  $p$ ; that is,  $s = kp$  where  $k$  is EVEN. A twin peak with  $s = kp$  is called a  $kp$ -twin peak. Thus we can speak of  $2p$ -twin peaks,  $4p$ -twin peaks, etc. A  $kp$ -twin peak is fully specified by  $k$ ,  $p$ , and  $x$ , from which we can easily compute  $y \equiv x + kp$ .

The set of  $kp$ -twin peaks is periodic with period  $q = p\#$ , where  $p\#$  is the PRIMORIAL of  $p$ . That is, if  $(x, y)$  is a  $kp$ -twin peak, then so is  $(x + q, y + q)$ . A fundamental  $kp$ -twin peak is a twin peak having  $x$  in the fundamental period  $[0, q)$ . The set of fundamental  $kp$ -twin peaks is symmetric with respect to the fundamental period; that is, if  $(x, y)$  is a twin peak on  $[0, q)$ , then so is  $(q - y, q - x)$ .

The question of the EXISTENCE of twin peaks was first raised by David Wilson in the math-fun mailing list on Feb. 10, 1997. Wilson already had privately showed the EXISTENCE of twin peaks of height  $p \leq 13$  to be unlikely, but was unable to rule them out altogether. Later that same day, John H. Conway, Johan de Jong, Derek Smith, and Manjul Bhargava collaborated to discover the first twin peak. Two hours at the blackboard revealed that  $p = 113$  admits the  $2p$ -twin peak

$$x = 126972592296404970720882679404584182254788131,$$

which settled the EXISTENCE question. Immediately thereafter, Fred Helenius found the smaller  $2p$ -twin peak with  $p = 89$  and

$$x = 9503844926749390990454854843625839.$$

The effort now shifted to finding the least PRIME  $p$  admitting a  $2p$ -twin peak. On Feb. 12, 1997, Fred Helenius found  $p = 71$ , which admits 240 fundamental  $2p$ -twin peaks, the least being

$$x = 7310131732015251470110369.$$

Helenius's results were confirmed by Dan Hoey, who also computed the least  $2p$ -twin peak  $L(2p)$  and number of fundamental  $2p$ -twin peaks  $N(2p)$  for  $p = 73, 79$ , and  $83$ . His results are summarized in the following table.

$p$	$L(2p)$	$N(2p)$
71	7310131732015251470110369	240
73	2061519317176132799110061	40296
79	3756800873017263196139951	164440
83	6316254452384500173544921	6625240

The  $2p$ -twin peak of height  $p = 73$  is the smallest known twin peak. Wilson found the smallest known  $4p$ -twin peak with  $p = 1327$ , as well as another very large  $4p$ -twin peak with  $p = 3203$ . Richard Schroepel noted that the latter twin peak is at the high end of its fundamental period and that its reflection within the fundamental period  $[0, p\#]$  is smaller.

Many open questions remain concerning twin peaks, e.g.,

1. What is the smallest twin peak (smallest  $n$ )?
2. What is the least PRIME  $p$  admitting a  $4p$ -twin peak?
3. Do  $6p$ -twin peaks exist?
4. Is there, as Conway has argued, an upper bound on the span of twin peaks?
5. Let  $p < q < r$  be PRIME. If  $p$  and  $r$  each admit  $kp$ -twin peaks, does  $q$  then necessarily admit a  $kp$ -twin peak?

see also ANDRICA'S CONJECTURE, DIVISOR FUNCTION, LEAST COMMON MULTIPLE, LEAST PRIME FACTOR

## Twin Prime Conjecture

Adding a correction proportional to  $1/\ln p$  to a computation of BRUN'S CONSTANT ending with  $\dots + 1/p + 1/(p+2)$  will give an estimate with error less than  $c(\sqrt{p} \ln p)^{-1}$ . An extended form of the conjecture states that

$$P_x(p, p+2) \sim 2\Pi_2 \int_2^x \frac{dx}{(\ln x)^2},$$

where  $\Pi_2$  is the TWIN PRIMES CONSTANT. The twin prime conjecture is a special case of the more general PRIME PATTERNS CONJECTURE corresponding to the set  $S = \{0, 2\}$ .

see also BRUN'S CONSTANT, PRIME ARITHMETIC PROGRESSION, PRIME CONSTELLATION, PRIME PATTERNS CONJECTURE, TWIN PRIMES

## Twin Primes

Twin primes are PRIMES  $(p, q)$  such that  $p - q = 2$ . The first few twin primes are  $n \pm 1$  for  $n = 4, 6, 12, 18, 30, 42, 60, 72, 102, 108, 138, 150, 180, 192, 198, 228, 240, 270, 282, \dots$  (Sloane's A014574). Explicitly, these are  $(3, 5), (5, 7), (11, 13), (17, 19), (29, 31), (41, 43), \dots$  (Sloane's A001359 and A006512).

Let  $\pi_2(n)$  be the number of twin primes  $p$  and  $p+2$  such that  $p \leq n$ . It is not known if there are an infinite number of such PRIMES (Shanks 1993), but all twin primes except  $(3, 5)$  are of the form  $6n \pm 1$ . J. R. Chen has shown there exists an INFINITE number of PRIMES  $p$  such that  $p+2$  has at most two factors (Le Lionnais 1983, p. 49). Brun proved that there exists a computable INTEGER  $x_0$  such that if  $x \geq x_0$ , then

$$\pi_2(x) < \frac{100x}{(\ln x)^2} \quad (1)$$

(Ribenoim 1989, p. 201). It has been shown that

$$\pi_2(x) \leq c \prod_{p>2} \left[ 1 - \frac{1}{(p-1)^2} \right] \frac{x}{(\ln x)^2} \left[ 1 + \mathcal{O}\left(\frac{\ln \ln x}{\ln x}\right) \right], \quad (2)$$

where  $c$  has been reduced to  $68/9 \approx 7.5556$  (Fouvry and Iwaniec 1983),  $128/17 \approx 7.5294$  (Fouvry 1984),  $7$  (Bombieri *et al.* 1986),  $6.9075$  (Fouvry and Grupp 1986), and  $6.8354$  (Wu 1990). The bound on  $c$  is further reduced to  $6.8324107886$  in a forthcoming thesis by Haugland (1998). This calculation involved evaluation of 7-fold integrals and fitting of three different parameters. Hardy and Littlewood conjectured that  $c = 2$  (Ribenoim 1989, p. 202).

Define

$$E \equiv \liminf_{n \rightarrow \infty} \frac{p_{n+1} - p_n}{\ln p_n}. \quad (3)$$

If there are an infinite number of twin primes, then  $E = 0$ . The best upper limit to date is  $E \leq \frac{1}{4} + \pi/16 = 0.44634\dots$  (Huxley 1973, 1977). The best previous values were  $15/16$  (Ricci),  $(2 + \sqrt{3})/8 = 0.46650\dots$  (Bombieri and Davenport 1966), and  $(2\sqrt{2} - 1)/4 = 0.45706\dots$  (Pil'Tai 1972), as quoted in Le Lionnais (1983, p. 26).

Some large twin primes are  $10,006,428 \pm 1$ ,  $1,706,595 \times 2^{11235} \pm 1$ , and  $571,305 \times 2^{7701} \pm 1$ . An up-to-date table of known twin primes with 2000 or more digits follows. An extensive list is maintained by Caldwell.

$(p, p+1)$	dig.	Reference
$260,497,545 \times 2^{6625} \pm 1$	2003	Atkin & Rickert 1984

$570,918,348 \cdot 10^{5120} \pm 1$	5129	Dubner 1995
$242,206,083 \cdot 2^{38880} \pm 1$	11713	Indlekofer & Ja'rai 1995

The last of these is the largest known twin prime pair. In 1995, Nicely discovered a flaw in the Intel® Pentium™ microprocessor by computing the reciprocals of 824,633,702,441 and 824,633,702,443, which should have been accurate to 19 decimal places but were incorrect from the tenth decimal place on (Cipra 1995, 1996; Nicely 1996).

If  $n \geq 2$ , the INTEGERS  $n$  and  $n + 2$  form a pair of twin primes IFF

$$4[(n-1)! + 1] + n \equiv 0 \pmod{n(n+2)}. \quad (4)$$

$n = pp'$  where  $(p, p')$  is a pair of twin primes IFF

$$\phi(n)\sigma(n) = (n-3)(n+1) \quad (5)$$

(Ribenoim 1989). The values of  $\pi_2(n)$  were found by Brent (1976) up to  $n = 10^{11}$ . T. Nicely calculated them up to  $10^{14}$  in his calculation of BRUN'S CONSTANT. The following table gives the number less than increasing powers of 10 (Sloane's A007508).

$n$	$\pi_2(n)$
$10^3$	35
$10^4$	205
$10^5$	1224
$10^6$	8,169
$10^7$	58,980
$10^8$	440,312
$10^9$	3,424,506
$10^{10}$	27,412,679
$10^{11}$	224,376,048
$10^{12}$	1,870,585,220
$10^{13}$	15,834,664,872
$10^{14}$	135,780,321,665

#### Twin Primes Constant

The twin primes constant  $\Pi_2$  is defined by

$$\Pi_2 \equiv \prod_{\substack{p > 2 \\ p \text{ prime}}} \left[ 1 - \frac{1}{(p-1)^2} \right] \quad (1)$$

$$\begin{aligned} \ln(\tfrac{1}{2}\Pi_2) &= \sum_{\substack{p \geq 3 \\ p \text{ prime}}} \ln \left[ \frac{p(p-2)}{(p-1)^2} \right] \\ &= \sum_{\substack{p \geq 3 \\ p \text{ prime}}} \left[ \ln \left( 1 - \frac{2}{p} \right) - 2 \ln \left( 1 - \frac{1}{p} \right) \right] \\ &= - \sum_{j=2}^{\infty} \frac{2^j - 2}{j} \sum_{\substack{p \geq 3 \\ p \text{ prime}}} p^{-j}, \end{aligned} \quad (2)$$

where the  $ps$  in sums and products are taken over PRIMES only. Flajolet and Vardi (1996) give series with accelerated convergence

$$\Pi_2 = \prod_{n=2}^{\infty} [\zeta(n)(1-2^{-n})]^{-I_n} \quad (3)$$

$$= \frac{3}{4} \frac{15}{16} \frac{35}{36} \prod_{n=2}^{\infty} [\zeta(n)(1-2^{-n})(1-3^{-n})(1-5^{-n}) \times (1-7^{-n})]^{-I_n}, \quad (4)$$

with

$$I_n \equiv \frac{1}{n} \sum_{d|n} \mu(d) 2^{n/d}, \quad (5)$$

where  $\mu(x)$  is the MÖBIUS FUNCTION. (4) has convergence like  $\sim (11/2)^{-n}$ .

The most accurately known value of  $\Pi_2$  is

$$\Pi_2 = 0.6601618158\dots \quad (6)$$

Le Lionnais (1983, p. 30) calls  $C_2$  the SHAH-WILSON CONSTANT, and  $2C_2$  the twin prime constant (Le Lionnais 1983, p. 37).

#### Twins

see BROTHERS, PAIR

#### Twirl

A ROTATION combined with an EXPANSION or DILATION.

see also SCREW, SHIFT

#### Twist

The twist of a ribbon measures how much it twists around its axis and is defined as the integral of the incremental twist around the ribbon. Letting  $Lk$  be the linking number of the two components of a ribbon,  $Tw$  be the twist, and  $Wr$  be the WRITHE, then

$$Lk(R) = Tw(R) + Wr(R)$$

(Adams 1994, p. 187).

**Type**

Whitehead and Russell (1927) devised a hierarchy of "types" in order to eliminate self-referential statements from *Principia Mathematica*, which purported to derive all of mathematics from logic. A set of the lowest type contained only objects (not sets), a set of the next higher type could contain only objects or sets of the lower type, and so on. Unfortunately, GÖDEL'S INCOMPLETENESS THEOREM showed that both *Principia Mathematica* and all consistent formal systems must be incomplete.

## Ulam Number

see ULAM SEQUENCE

## Ulam's Problem

see COLLATZ PROBLEM

## Ulam Sequence

The Ulam sequence  $\{a_i\} = (u, v)$  is defined by  $a_1 = u$ ,  $a_2 = v$ , with the general term  $a_n$  for  $n > 2$  given by the least INTEGER expressible uniquely as the SUM of two distinct earlier terms. The numbers so produced are sometimes called U-NUMBERS or ULAM NUMBERS.

The first few numbers in the (1, 2) Ulam sequence are 1, 2, 3, 4, 6, 8, 11, 13, 16, ... (Sloane's A002858). Here, the first term after the initial 1, 2 is obviously 3 since  $3 = 1 + 2$ . The next term is  $4 = 1 + 3$ . (We don't have to worry about  $4 = 2 + 2$  since it is a sum of a single term instead of *unique* terms.) 5 is not a member of the sequence since it is representable in *two* ways,  $5 = 1 + 4 = 2 + 3$ , but  $6 = 2 + 4$  is a member.

Proceeding in the manner, we can generate Ulam sequences for any  $(u, v)$ , examples of which are given below.

$$\begin{aligned}(1, 2) &= \{1, 2, 3, 4, 6, 8, 11, 13, 16, 18, \dots\} \\ (1, 3) &= \{1, 3, 4, 5, 6, 8, 10, 12, 17, 21, \dots\} \\ (1, 4) &= \{1, 4, 5, 6, 7, 8, 10, 16, 18, 19, \dots\} \\ (1, 5) &= \{1, 5, 6, 7, 8, 9, 10, 12, 20, 22, \dots\} \\ (2, 3) &= \{2, 3, 5, 7, 8, 9, 13, 14, 18, 19, \dots\} \\ (2, 4) &= \{2, 4, 6, 8, 12, 16, 22, 26, 32, 36, \dots\} \\ (2, 5) &= \{2, 5, 7, 9, 11, 12, 13, 15, 19, 23, \dots\}.\end{aligned}$$

Schmerl and Spiegel (1994) proved that Ulam sequences  $(2, v)$  for ODD  $v \geq 5$  have exactly two EVEN terms. Ulam sequences with only finitely many EVEN terms eventually must have periodic successive differences (Finch 1991, 1992abc). Cassaigne and Finch (1995) proved that the Ulam sequences  $(4, v)$  for  $5 \leq v \equiv 1 \pmod{4}$  have exactly three EVEN terms.

The Ulam sequence can be generalized by the *s*-ADDITIVE SEQUENCE.

see also GREEDY ALGORITHM, *s*-ADDITIVE SEQUENCE, STÖHR SEQUENCE

## Ultrametric

An ultrametric is a METRIC which satisfies the following strengthened version of the TRIANGLE INEQUALITY,

$$d(x, z) \leq \max(d(x, y), d(y, z))$$

for all  $x, y, z$ . At least two of  $d(x, y)$ ,  $d(y, z)$ , and  $d(x, z)$  are the same.

Let  $X$  be a SET, and let  $X^{\mathbb{N}}$  (where  $\mathbb{N}$  is the SET of NATURAL NUMBERS) denote the collection of sequences of elements of  $X$  (i.e., all the possible sequences  $x_1, x_2, x_3, \dots$ ). For sequences  $a = (a_1, a_2, \dots)$ ,  $b = (b_1, b_2, \dots)$ , let  $n$  be the number of initial places where the sequences agree, i.e.,  $a_1 = b_1, a_2 = b_2, \dots, a_n = b_n$ , but  $a_{n+1} \neq b_{n+1}$ . Take  $n = 0$  if  $a_1 \neq b_1$ . Then defining  $d(a, b) = 2^{-n}$  gives an ultrametric.

The  $p$ -ADIC NUMBER metric is another example of an ultrametric.

see also METRIC,  $p$ -ADIC NUMBER

### Ultraradical

A symbol which can be used to express solutions not obtainable by finite ROOT extraction. The solution to the irreducible QUINTIC EQUATION

$$x^5 + x = a$$

is written  $\sqrt[5]{a}$ .

see also RADICAL

### Ultraspherical Differential Equation

$$(1 - x^2)y'' - (2\alpha + 1)xy' + n(n + 2\alpha)y = 0. \quad (1)$$

Alternate forms are

$$(1 - x^2)Y'' + (2\lambda - 3)xY' + (n + 1)(n + 2\lambda - 1)Y = 0, \quad (2)$$

where

$$Y = (1 - x^2)^{\lambda-1/2} P_n^{(\lambda)}(x), \quad (3)$$

$$\frac{d^2 u}{dx^2} + \left[ \frac{(n + \lambda)^2}{1 - x^2} + \frac{\frac{1}{2} + \lambda - \lambda^2 + \frac{1}{4}x^2}{(1 - x^2)^2} \right] u = 0, \quad (4)$$

where

$$u = (1 - x^2)^{\lambda/2+1/4} P_n^{(\lambda)}(x), \quad (5)$$

and

$$\frac{d^2 u}{d\theta^2} + \left[ (n + \lambda)^2 + \frac{\lambda(1 - \lambda)}{\sin^2 \theta} \right] u = 0, \quad (6)$$

where

$$u = \sin^\lambda \theta P_n^{(\lambda)}(\cos \theta). \quad (7)$$

The solutions are the ULTRASPHERICAL FUNCTIONS  $P_n^{(\lambda)}(x)$ . For integral  $n$  with  $\alpha < 1/2$ , the function converges to the ULTRASPHERICAL POLYNOMIALS  $C_n^{(\alpha)}(x)$ .

### References

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics*, Part I. New York: McGraw-Hill, pp. 547-549, 1953.

### Ultraspherical Function

A function defined by a POWER SERIES whose coefficients satisfy the RECURRENCE RELATION

$$a_{j+2} = a_j \frac{(k + j)(k + j + 2\alpha) - n(n + 2\alpha)}{(k + j + 1)(k + j + 2)}.$$

For  $x \neq -1$ , the function converges for  $\alpha < 1/2$  and diverges for  $\alpha > 1/2$ .

### Ultraspherical Polynomial

The ultraspherical polynomials are solutions  $P_n^{(\lambda)}(x)$  to the ULTRASPHERICAL DIFFERENTIAL EQUATION for INTEGER  $n$  and  $\alpha < 1/2$ . They are generalizations of LEGENDRE POLYNOMIALS to  $(n + 2)$ -D space and are proportional to (or, depending on the normalization, equal to) the GEGENBAUER POLYNOMIALS  $C_n^{(\lambda)}(x)$ , denoted in *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) `GegenbauerC[n, lambda, x]`. The ultraspherical polynomials are also JACOBI POLYNOMIALS with  $\alpha = \beta$ . They are given by the GENERATING FUNCTION

$$\frac{1}{(1 - 2xt + t^2)^\lambda} = \sum_{n=0}^{\infty} P_n^{(\lambda)}(x) t^n, \quad (1)$$

and can be given explicitly by

$$P_n^{(\lambda)}(x) = \frac{\Gamma(\lambda + \frac{1}{2})}{\Gamma(2\lambda)} \frac{\Gamma(n + 2\lambda)}{\Gamma(n + \lambda + \frac{1}{2})} P_n^{(\lambda-1/2, \lambda-1/2)}(x), \quad (2)$$

where  $P_n^{(\lambda-1/2, \lambda-1/2)}$  is a JACOBI POLYNOMIAL (Szegő 1975, p. 80). The first few ultraspherical polynomials are

$$P_0^{(\lambda)}(x) = 1 \quad (3)$$

$$P_1^{(\lambda)}(x) = 2\lambda x \quad (4)$$

$$P_2^{(\lambda)}(x) = -\lambda + 2\lambda(1 + \lambda)x^2 \quad (5)$$

$$P_3^{(\lambda)}(x) = -2\lambda(1 + \lambda)x + \frac{4}{3}\lambda(1 + \lambda)(2 + \lambda)x^3. \quad (6)$$

In terms of the HYPERGEOMETRIC FUNCTIONS,

$$\begin{aligned} P_n^{(\lambda)}(x) &= \binom{n + 2\lambda - 1}{n} \\ &\times {}_2F_1\left(-n, n + 2\lambda; \lambda + \frac{1}{2}; \frac{1}{2}(1 - x)\right) \\ &= 2^n \binom{n + \lambda - 1}{n} (x - 1)^n \\ &\times {}_2F_1\left(-n, -n - \lambda + \frac{1}{2}; -2n - 2\lambda + 1; \frac{2}{1 - x}\right) \end{aligned} \quad (7)$$

$$\begin{aligned} &= \binom{n + 2\lambda + 1}{n} \left(\frac{x + 1}{2}\right)^n \\ &\times {}_2F_1\left(-n, -n - \lambda + \frac{1}{2}; \lambda + \frac{1}{2}; \frac{x - 1}{x + 1}\right). \end{aligned} \quad (9)$$

They are normalized by

$$\int_{-1}^1 (1-x^2)^{\lambda-1/2} [P_n^{(\lambda)}]^2 dx = 2^{1-2\lambda} \pi \frac{\Gamma(n+2\lambda)}{(n+\lambda)\Gamma^2(\lambda)\Gamma(n+1)}. \quad (10)$$

Derivative identities include

$$\frac{d}{dx} P_n^{(\lambda)}(x) = 2\lambda P_{n-1}^{(\lambda+1)}(x) \quad (11)$$

$$(1-x^2) \frac{d}{dx} [P_n^{(\lambda)}] = [2(n+\lambda)]^{-1} [(n+2\lambda-1) \times (n+2\lambda) P_{n-1}^{(\lambda)}(x) - n(n+1) P_{n+1}^{(\lambda)}(x)] \quad (12)$$

$$= -nx P_n^{(\lambda)}(x) + (n+2\lambda-1) P_{n-1}^{(\lambda)}(x) \quad (13)$$

$$= (n+2\lambda) x P_n^{(\lambda)}(x) - (n+1) P_{n+1}^{(\lambda)}(x) \quad (14)$$

$$nP_n^{(\lambda)}(x) = x \frac{d}{dx} [P_n^{(\lambda)}(x)] - \frac{d}{dx} [P_{n-1}^{(\lambda)}(x)] \quad (15)$$

$$(n+2\lambda) P_n^{(\lambda)}(x) = \frac{d}{dx} [P_{n+1}^{(\lambda)}(x)] - x \frac{d}{dx} [P_n^{(\lambda)}(x)] \quad (16)$$

$$\frac{d}{dx} [P_{n+1}^{(\lambda)}(x) - P_{n-1}^{(\lambda)}(x)] = 2(n+\lambda) P_n^{(\lambda)} P_n^{(\lambda)}(x) \quad (17)$$

$$= 2\lambda [P_n^{(\lambda+1)}(x) - P_{n-2}^{(\lambda+1)}(x)] \quad (18)$$

(Szegő 1975, pp. 80–83).

A RECURRENCE RELATION is

$$nP_n^{(\lambda)}(x) = 2(n+\lambda-1)xP_{n-1}^{(\lambda)}(x) - (n+2\lambda-2)P_{n-2}^{(\lambda)}(x) \quad (19)$$

for  $n = 2, 3, \dots$

Special double- $\nu$  FORMULAS also exist

$$P_{2\nu}^{(\lambda)}(x) = \binom{2\nu+2\lambda-1}{2\nu} {}_2F_1(-\nu, \nu+\lambda; \lambda+\frac{1}{2}; 1-x^2) \quad (20)$$

$$= (-1)^\nu \binom{\nu+\lambda-1}{\nu} {}_2F_1(-\nu, \nu+\lambda; \frac{1}{2}; x^2) \quad (21)$$

$$P_{2\nu+1}^{(\lambda)}(x) = \binom{2\nu+2\lambda}{2\nu+1} x {}_2F_1(-\nu, \nu+\lambda+1; \lambda+\frac{1}{2}; 1-x^2) \quad (22)$$

$$= (-1)^\nu 2\lambda \binom{\nu+\lambda}{\nu} x {}_2F_1(-\nu, \nu+\lambda+1; \frac{3}{2}; x^2). \quad (23)$$

Special values are given in the following table.

$\lambda$	Special Polynomial
$\frac{1}{2}$	Legendre
1	Chebyshev polynomial of the second kind

Koschmieder (1920) gives representations in terms of ELLIPTIC FUNCTIONS for  $\alpha = -3/4$  and  $\alpha = -2/3$ .

see also BIRTHDAY PROBLEM, CHEBYSHEV POLYNOMIAL OF THE SECOND KIND, ELLIPTIC FUNCTION, HYPERGEOMETRIC FUNCTION, JACOBI POLYNOMIAL

## Umbilic Point

A point on a surface at which the CURVATURE is the same in any direction.

## Umbral Calculus

The study of certain properties of FINITE DIFFERENCES. The term was coined by Sylvester from the word "umbra" (meaning "shadow" in Latin), and reflects the fact that for many types of identities involving sequences of polynomials with POWERS  $a^n$ , "shadow" identities are obtained when the polynomials are changed to discrete values and the exponent in  $a^n$  is changed to the POCHHAMMER SYMBOL  $(a)_n \equiv a(a-1)\cdots(a-n+1)$ .

For example, NEWTON'S FORWARD DIFFERENCE FORMULA written in the form

$$f(x+a) = \sum_{n=0}^{\infty} \frac{(a)_n \Delta^n f(x)}{n!} \quad (1)$$

with  $f(x+a) \equiv f_{x+a}$  looks suspiciously like a finite analog of the TAYLOR SERIES expansion

$$f(x+a) = \sum_{n=0}^{\infty} \frac{a^n \tilde{D}^n f(x)}{n!}, \quad (2)$$

where  $\tilde{D}$  is the DIFFERENTIAL OPERATOR. Similarly, the CHU-VANDERMONDE IDENTITY

$$(x+a)_n = \sum_{k=0}^{\infty} \binom{n}{k} (a)_k (x)_{n-k} \quad (3)$$

with  $\binom{n}{k}$  a BINOMIAL COEFFICIENT, looks suspiciously like an analog of the BINOMIAL THEOREM

$$(x+a)^n = \sum_{k=0}^{\infty} \binom{n}{k} a^k x^{n-k} \quad (4)$$

(Di Bucchianico and Loeb).

see also BINOMIAL THEOREM, CHU-VANDERMONDE IDENTITY, FINITE DIFFERENCE

### Uncorrelated

Variables  $x_i$  and  $x_j$  are said to be uncorrelated if their COVARIANCE is zero:

$$\text{cov}(x_i, x_j) = 0.$$

INDEPENDENT STATISTICS are always uncorrelated, but the converse is not necessarily true.

see also COVARIANCE, INDEPENDENT STATISTICS

### Uncountable Set

see UNCOUNTABLY INFINITE SET

### Uncountably Infinite Set

An INFINITE SET which is not a COUNTABLY INFINITE SET.

see also ALEPH-0, ALEPH-1, COUNTABLE SET, COUNTABLY INFINITE SET, FINITE, INFINITE

### Undecagon

The unconstructible 11-sided POLYGON with SCHLÄFLI SYMBOL {11}.

see also DECAGON, DODECAGON, TRIGONOMETRY VALUES— $\pi/11$

### Undecidable

Not DECIDABLE as a result of being neither formally provable nor unprovable.

see also GÖDEL'S INCOMPLETENESS THEOREM, RICHARDSON'S THEOREM

### Undecillion

In the American system,  $10^{36}$ .

see also LARGE NUMBER

### Undetermined Coefficients Method

Given a nonhomogeneous ORDINARY DIFFERENTIAL EQUATION, select a differential operator which will annihilate the right side, and apply it to both sides. Find the solution to the homogeneous equation, plug it into the left side of the original equation, and solve for constants by setting it equal to the right side. The solution is then obtained by plugging the determined constants into the homogeneous equation.

see also ORDINARY DIFFERENTIAL EQUATION

### Undulating Number

A number of the form  $aba \dots$ ,  $abab \dots$ , etc. The first few nontrivial undulants (with the stipulation that  $a \neq b$ ) are 101, 121, 131, 141, 151, 161, 171, 181, 191, 202, 212, ... (Sloane's A046075). Including the trivial 1- and 2-digit undulants and dropping the requirement that  $a \neq b$  gives Sloane's A033619.

The first few undulating SQUARES are 121, 484, 676, 69696, ... (Sloane's A016073), with no larger such numbers of fewer than a million digits (Pickover 1995). Several tricks can be used to speed the search for square undulating numbers, especially by examining the possible patterns of ending digits. For example, the only possible sets of four trailing digits for undulating SQUARES are 0404, 1616, 2121, 2929, 3636, 6161, 6464, 6969, 8484, and 9696.

The only undulating POWER  $n^p = aba \dots$  for  $3 \leq p \leq 31$  and up to 100 digits is  $7^3 = 343$  (Pickover 1995). A large undulating prime is given by  $7 + 720(100^{49} - 1)/99$  (Pickover 1995).

A binary undulant is a POWER of 2 whose base-10 representation contains one or both of the sequences 010... and 101... The first few are  $2^n$  for  $n = 103, 107, 138, 159, 179, 187, 192, 199, 205, \dots$  (Sloane's A046076). The smallest  $n$  for which an undulating sequence of *exactly*  $d$ -digit occurs for  $d = 3, 4, \dots$  are  $n = 103, 138, 875, 949, 6617, 1802, 14545, \dots$  (Sloane's A046077). An undulating binary sequence of length 10 occurs for  $n = 1, 748, 219$  (Pickover 1995).

### Unduloid

A SURFACE OF REVOLUTION with constant NONZERO MEAN CURVATURE also called an ONDULOID. It is a ROULETTE obtained from the path described by the FOCI of a CONIC SECTION when rolled on a LINE. This curve then generates an unduloid when revolved about the LINE. These curves are special cases of the shapes assumed by soap film spanning the gap between prescribed boundaries. The unduloid of a PARABOLA gives a CATENOID.

### Unexpected Hanging Paradox

A PARADOX also known as the SURPRISE EXAMINATION PARADOX or PREDICTION PARADOX.

A prisoner is told that he will be hanged on some day between Monday and Friday, but that he will not know on which day the hanging will occur before it happens. He cannot be hanged on Friday, because if he were still alive on Thursday, he would know that the hanging will occur on Friday, but he has been told he will not know the day of his hanging in advance. He cannot be hanged Thursday for the same reason, and the same argument

shows that he cannot be hanged on any other day. Nevertheless, the executioner unexpectedly arrives on some day other than Friday, surprising the prisoner.

This PARADOX is similar to that in Robert Louis Stevenson's "The Imp in the Bottle," in which you are offered the opportunity to buy, for whatever price you wish, a bottle containing a genie who will fulfill your every desire. The only catch is that the bottle must thereafter be resold for a price smaller than what you paid for it, or you will be condemned to live out the rest of your days in excruciating torment. Obviously, no one would buy the bottle for 1¢ since he would have to give the bottle away, but no one would accept the bottle knowing he would be unable to get rid of it. Similarly, no one would buy it for 2¢, and so on. However, for some reasonably large amount, it will always be possible to find a next buyer, so the bottle will be bought (Paulos 1995).

### Unfinished Game

see SHARING PROBLEM

### Unhappy Number

A number which is not HAPPY is said to be unhappy.

see also HAPPY NUMBER

### Unicursal Circuit

A CIRCUIT in which an entire GRAPH is traversed in one route. An example of a curve which can be traced unicursally is the MOHAMMED SIGN.

### Uniform Apodization Function

An APODIZATION FUNCTION

$$f(x) = 1, \quad (1)$$

having INSTRUMENT FUNCTION

$$\begin{aligned} I(x) &= \int_{-a}^a e^{-2\pi i k x} dx = -\frac{1}{2\pi i k} (e^{-2\pi i k a} - e^{2\pi i k x}) \\ &= \frac{\sin(2\pi k a)}{\pi k} = 2a \operatorname{sinc}(2\pi k a). \end{aligned} \quad (2)$$

The peak (in units of  $a$ ) is 2. The extrema are given by letting  $\beta \equiv 2\pi k a$  and solving

$$\frac{d}{d\beta}(\beta \sin \beta) = \frac{\sin \beta - \beta \cos \beta}{\beta^2} = 0 \quad (3)$$

$$\sin \beta - \beta \cos \beta = 0 \quad (4)$$

$$\tan \beta = \beta. \quad (5)$$

Solving this numerically gives  $\beta_0 = 0$ ,  $\beta_1 = 4.49341$ ,  $\beta_2 = 7.72525$ , ... for the first few solutions. The second of these is the peak POSITIVE sidelobe, and the third is the peak NEGATIVE sidelobe. As a fraction of the peak, they are 0.128375 and  $-0.217234$ . The FULL WIDTH AT HALF MAXIMUM is found by setting  $I(x) = 1$

$$\operatorname{sinc}(x) = \frac{1}{2}, \quad (6)$$

and solving for  $x_{1/2}$ , yielding

$$x_{1/2} = 2\pi k_{1/2} a = 1.89549. \quad (7)$$

Therefore, with  $L \equiv 2a$ ,

$$\text{FWHM} = 2k_{1/2} = \frac{0.603353}{a} = \frac{1.20671}{L}. \quad (8)$$

see also APODIZATION FUNCTION

### Uniform Boundedness Principle

If a "pointwise-bounded" family of continuous linear OPERATORS from a BANACH SPACE to a NORMED SPACE is "uniformly bounded." Symbolically, if  $\sup \|T_i(x)\|$  is FINITE for each  $x$  in the unit BALL, then  $\sup \|T_i\|$  is FINITE. The theorem is also called the BANACH-STEINHAUS THEOREM.

#### References

Zeidler, E. *Applied Functional Analysis: Applications to Mathematical Physics*. New York: Springer-Verlag, 1995.

### Uniform Convergence

A SERIES  $\sum_{n=1}^{\infty} u_n(x)$  is uniformly convergent to  $S(x)$  for a set  $E$  of values of  $x$  if, for each  $\epsilon > 0$ , an INTEGER  $N$  can be found such that

$$|S_n(x) - S(x)| < \epsilon \quad (1)$$

for  $n \geq N$  and all  $x \in E$ . To test for uniform convergence, use ABEL'S UNIFORM CONVERGENCE TEST or the WEIERSTRASS M-TEST. If individual terms  $u_n(x)$  of a uniformly converging series are continuous, then

1. The series sum

$$f(x) = \sum_{n=1}^{\infty} u_n(x) \quad (2)$$

is continuous,

2. The series may be integrated term by term

$$\int_a^b f(x) dx = \sum_{n=1}^{\infty} \int_a^b u_n(x) dx, \quad (3)$$

and

3. The series may be differentiated term by term

$$\frac{d}{dx} f(x) = \sum_{n=1}^{\infty} n \frac{d}{dx} u_n(x). \quad (4)$$

see also ABEL'S THEOREM, ABEL'S UNIFORM CONVERGENCE TEST, WEIERSTRASS M-TEST

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 299–301, 1985.

### Uniform Distribution

A distribution which has constant probability is called a uniform distribution, sometimes also called a RECTANGULAR DISTRIBUTION. The probability density function and cumulative distribution function for a continuous uniform distribution are

$$P(x) = \begin{cases} \frac{1}{b-a} & \text{for } a < x < b \\ 0 & \text{for } x < a, x > b \end{cases} \quad (1)$$

$$D(x) = \begin{cases} 0 & \text{for } x < a \\ \frac{x-a}{b-a} & \text{for } a \leq x < b \\ 1 & \text{for } x \geq b. \end{cases} \quad (2)$$

With  $a = 0$  and  $b = 1$ , these can be written

$$P(x) = \frac{1}{2} \operatorname{sgn}(x) - \operatorname{sgn}(x-1) \quad (3)$$

$$D(x) = \frac{1}{2} [1 - (1-x)^2 \operatorname{sgn}(1-x) + x \operatorname{sgn}(x)]. \quad (4)$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = \frac{2}{ht} \sin\left(\frac{1}{2}ht\right) e^{imt}, \quad (5)$$

where

$$a = m - \frac{1}{2}h \quad (6)$$

$$b = m + \frac{1}{2}h. \quad (7)$$

The MOMENT-GENERATING FUNCTION is

$$M(t) = \langle e^{xt} \rangle = \int_a^b \frac{e^{xt}}{b-a} dx = \left[ \frac{e^{xt}}{t(b-a)} \right]_a^b, \quad (8)$$

so

$$M(t) = \begin{cases} \frac{e^{tb} - e^{ta}}{t(b-a)} & \text{for } t \neq 0 \\ 0 & \text{for } t = 0, \end{cases} \quad (9)$$

and

$$\begin{aligned} M'(t) &= \frac{1}{b-a} \left[ \frac{1}{t} (be^{bt} - ae^{at}) - \frac{1}{t^2} (e^{bt} - e^{at}) \right] \\ &= \frac{e^{bt}(bt-1) - e^{at}(at-1)}{(b-a)t^2}. \end{aligned} \quad (10)$$

The function is not differentiable at zero, so the MOMENTS cannot be found using the standard technique. They can, however, be found by direct integration. The MOMENTS about 0 are

$$\mu'_1 = \frac{1}{2}(a+b) \quad (11)$$

$$\mu'_2 = \frac{1}{3}(a^2 + ab + b^2) \quad (12)$$

$$\mu'_3 = \frac{1}{4}(a+b)(a^2 + b^2) \quad (13)$$

$$\mu'_4 = \frac{1}{5}(a^4 + a^3b + a^2b^2 + ab^3 + b^4). \quad (14)$$

The MOMENTS about the MEAN are

$$\mu_1 = 0 \quad (15)$$

$$\mu_2 = \frac{1}{12}(b-a)^2 \quad (16)$$

$$\mu_3 = 0 \quad (17)$$

$$\mu_4 = \frac{1}{80}(b-a)^4, \quad (18)$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \frac{1}{2}(a+b) \quad (19)$$

$$\sigma^2 = \mu_2 = \frac{1}{12}(b-a)^2 \quad (20)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^{3/2}} = 0 \quad (21)$$

$$\gamma_2 = -\frac{6}{5}. \quad (22)$$

The probability distribution function and cumulative distributions function for a *discrete* uniform distribution are

$$P(n) = \frac{1}{N} \quad (23)$$

$$D(n) = \frac{n}{N} \quad (24)$$

for  $n = 1, \dots, N$ . The MOMENT-GENERATING FUNCTION is

$$\begin{aligned} M(t) &= \langle e^{nt} \rangle = \sum_{n=1}^N \frac{1}{N} e^{nt} = \frac{1}{N} \frac{e^t - e^{t(N+1)}}{1 - e^t} \\ &= \frac{e^t(1 - e^{Nt})}{N(1 - e^t)}. \end{aligned} \quad (25)$$

The MOMENTS about 0 are

$$\mu'_m = \frac{1}{N} \sum_{n=1}^N n^m, \quad (26)$$

so

$$\mu'_1 = \frac{1}{2}(N+1) \quad (27)$$

$$\mu'_2 = \frac{1}{6}(N+1)(2N+1) \quad (28)$$

$$\mu'_3 = \frac{1}{4}N(N+1)^2 \quad (29)$$

$$\mu'_4 = \frac{1}{30}(N+1)(2N+1)(3N^2 + 3N - 1), \quad (30)$$

and the MOMENTS about the MEAN are

$$\mu_2 = \frac{1}{12}(N-1)(N+1) \quad (31)$$

$$\mu_3 = 0 \quad (32)$$

$$\mu_4 = \frac{1}{240}(N-1)(N+1)(3N^2 - 7). \quad (33)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \frac{1}{2}(N+1) \quad (34)$$

$$\sigma^2 = \mu_2 = \frac{1}{12}(N-1)(N+1) \quad (35)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^{3/2}} = 0 \quad (36)$$

$$\gamma_2 = \frac{6(N^2 + 1)}{5(N-1)(N+1)}. \quad (37)$$

## Uniform Polyhedron

The uniform polyhedra are POLYHEDRA with identical VERTICES. Coxeter *et al.* (1954) conjectured that there are 75 such polyhedra in which only two faces are allowed to meet at an EDGE, and this was subsequently proven. (However, when any EVEN number of faces may meet, there are 76 polyhedra.) If the five pentagonal PRISMS are included, the number rises to 80.

The VERTICES of a uniform polyhedron all lie on a SPHERE whose center is their CENTROID. The VERTICES joined to another VERTEX lie on a CIRCLE.

Source code and binary programs for generating and viewing the uniform polyhedra are also available at <http://www.math.technion.ac.il/~rl/kaleido/>. The following depictions of the polyhedra were produced by R. Maeder's **UniformPolyhedra.m** package for *Mathematica*® (Wolfram Research, Champaign, IL). Due to a limitation in *Mathematica*'s renderer, uniform polyhedra 69, 72, 74, and 75 cannot be displayed using this package.

## Uniform Variate

A RANDOM NUMBER which lies within a specified range (which can, without loss of generality, be taken as [0, 1]), with a UNIFORM DISTRIBUTION.

## References

- Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Uniform Deviates." §7.1 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 267-277, 1992.

## Unimodal Distribution

A DISTRIBUTION such as the GAUSSIAN DISTRIBUTION which has a single "peak."

see also BIMODAL DISTRIBUTION

## Unimodal Sequence

A finite SEQUENCE which first increases and then decreases. A SEQUENCE  $\{s_1, s_2, \dots, s_n\}$  is unimodal if there exists a  $t$  such that

$$s_1 \leq s_2 \leq \dots \leq s_t$$

and

$$s_t \geq s_{t+1} \geq \dots \geq s_n.$$

## Unimodular Group

A group whose left HAAR MEASURE equals its right HAAR MEASURE.

see also HAAR MEASURE

## References

- Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537-549, 1996.

## Unimodular Matrix

A MATRIX  $A$  with INTEGER elements and DETERMINANT  $\det(A) = \pm 1$ , also called a UNIT MATRIX.

The inverse of a unimodular matrix is another unimodular matrix. A POSITIVE unimodular matrix has  $\det(A) = +1$ . The  $n$ th POWER of a POSITIVE UNIMODULAR MATRIX

$$M \equiv \begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix} \quad (1)$$

is

$$M^n = \begin{bmatrix} m_{11}U_{n-1}(a) - U_{n-2}(a) & m_{12}U_{n-1}(a) \\ m_{21}U_{n-1}(a) & m_{22}U_{n-1}(a) - U_{n-2}(a) \end{bmatrix}, \quad (2)$$

where

$$a \equiv \frac{1}{2}(m_{11} + m_{22}) \quad (3)$$

and the  $U_n$  are CHEBYSHEV POLYNOMIALS OF THE SECOND KIND,

$$U_m(x) = \frac{\sin[(m+1)\cos^{-1}x]}{\sqrt{1-x^2}}. \quad (4)$$

see also CHEBYSHEV POLYNOMIAL OF THE SECOND KIND

## References

**Unimodular Transformation**

A transformation  $\mathbf{x}' = \mathbf{A}\mathbf{x}$  is unimodular if the DETERMINANT of the MATRIX  $\mathbf{A}$  satisfies

$$\det(\mathbf{A}) = \pm 1.$$

A NECESSARY and SUFFICIENT condition that a linear transformation transform a lattice to itself is that the transformation be unimodular.

**Union**

The union of two sets  $A$  and  $B$  is the set obtained by combining the members of each. This is written  $A \cup B$ , and is pronounced "A union B" or "A cup B." The union of sets  $A_1$  through  $A_n$  is written  $\bigcup_{i=1}^n A_i$ .

Let  $A, B, C, \dots$  be sets, and let  $P(S)$  denote the probability of  $S$ . Then

$$P(A \cup B) = P(A) + P(B) - P(A \cap B). \quad (1)$$

Similarly,

$$\begin{aligned} P(A \cup B \cup C) &= P[A \cup (B \cup C)] \\ &= P(A) + P(B \cup C) - P[A \cap (B \cup C)] \\ &= P(A) + [P(B) + P(C) - P(B \cap C)] \\ &\quad - P[(A \cap B) \cup (A \cap C)] \\ &= P(A) + P(B) + P(C) - P(B \cap C) \\ &\quad - \{P(A \cap B) + P(A \cap C) - P[(A \cap B) \cap (A \cap C)]\} \\ &= P(A) + P(B) + P(C) - P(A \cap B) \\ &\quad - P(A \cap C) - P(B \cap C) + P(A \cap B \cap C). \end{aligned} \quad (2)$$

If  $A$  and  $B$  are DISJOINT, by definition  $P(A \cap B) = 0$ , so

$$P(A \cup B) = P(A) + P(B). \quad (3)$$

Continuing, for a set of  $n$  disjoint elements  $E_1, E_2, \dots, E_n$

$$P\left(\bigcup_{i=1}^n E_i\right) = \sum_{i=1}^n P(E_i), \quad (4)$$

which is the COUNTABLE ADDITIVITY PROBABILITY AXIOM. Now let

$$E_i \equiv A \cap B_i, \quad (5)$$

then

$$P\left(\bigcup_{i=1}^n E \cap B_i\right) = \sum_{i=1}^n P(E \cap B_i). \quad (6)$$

see also INTERSECTION, OR

**Uniplanar Double Point**

see ISOLATED SINGULARITY

**Unipotent**

A  $p$ -ELEMENT  $x$  of a GROUP  $G$  is unipotent if  $F^*(C_G(x))$  is a  $p$ -GROUP, where  $F^*$  is the generalized FITTING SUBGROUP.

see also FITTING SUBGROUP,  $p$ -ELEMENT,  $p$ -GROUP

**Unique**

The property of being the only possible solution (perhaps modulo a constant, class of transformation, etc.).

see also ALEKSANDROV'S UNIQUENESS THEOREM, EXISTENCE, MAY-THOMASON UNIQUENESS THEOREM

**Unique Factorization Theorem**

see FUNDAMENTAL THEOREM OF ARITHMETIC

**Unit**

A unit is an element in a RING that has a multiplicative inverse. If  $n$  is an ALGEBRAIC INTEGER which divides every ALGEBRAIC INTEGER in the FIELD,  $n$  is called a unit in that FIELD. A given FIELD may contain an infinity of units. The units of  $\mathbb{Z}_n$  are the elements RELATIVELY PRIME to  $n$ . The units in  $\mathbb{Z}_n$  which are SQUARES are called QUADRATIC RESIDUES.

see also EISENSTEIN UNIT, FUNDAMENTAL UNIT, PRIME UNIT, QUADRATIC RESIDUE

**Unit Circle**

A CIRCLE of RADIUS 1, such as the one used to define the functions of TRIGONOMETRY.

see also UNIT DISK, UNIT SQUARE

**Unit Disk**

A DISK with RADIUS 1.

see also FIVE DISKS PROBLEM, UNIT CIRCLE, UNIT SQUARE

**Unit Fraction**

A unit fraction is a FRACTION with NUMERATOR 1, also known as an EGYPTIAN FRACTION. Any RATIONAL NUMBER has infinitely many unit fraction representations, although only finitely many have a given fixed number of terms. Each FRACTION  $x/y$  with  $y$  ODD has a unit fraction representation in which each DENOMINATOR is ODD (Breusch 1954; Guy 1994, p. 160). Every  $x/y$  has a  $t$ -term representation where  $t = \mathcal{O}(\sqrt{\log y})$  (Vose 1985).

There are a number of ALGORITHMS (including the BINARY REMAINDER METHOD, CONTINUED FRACTION UNIT FRACTION ALGORITHM, GENERALIZED REMAINDER METHOD, GREEDY ALGORITHM, REVERSE GREEDY ALGORITHM, SMALL MULTIPLE METHOD, and SPLITTING ALGORITHM) for decomposing an arbitrary FRACTION into unit fractions.

### Unit Ring

A unit ring is a set together with two BINARY OPERATORS  $S(+, *)$  satisfying the following conditions:

1. Additive associativity: For all  $a, b, c \in S$ ,  $(a+b)+c = a+(b+c)$ ,
2. Additive commutativity: For all  $a, b \in S$ ,  $a+b = b+a$ ,

3. Additive identity: There exists an element  $0 \in S$  such that for all  $a \in S$ :  $0+a = a+0 = a$ ,
4. Additive inverse: For every  $a \in S$ , there exists a  $-a \in S$  such that  $a+(-a) = (-a)+a = 0$ ,
5. Multiplicative associativity: For all  $a, b, c \in S$ ,  $(a*b)*c = a*(b*c)$ ,
6. Multiplicative identity: There exists an element  $1 \in S$  such that for all  $a \in S$ ,  $1*a = a*1 = a$ ,
7. Left and right distributivity: For all  $a, b, c \in S$ ,  $a*(b+c) = (a*b)+(a*c)$  and  $(b+c)*a = (b*a)+(c*a)$ .

Thus, a unit ring is a RING with a multiplicative identity.

### Unit Sphere

A SPHERE of RADIUS 1.

see also SPHERE, UNIT CIRCLE

### Unit Square

A SQUARE with side lengths 1. The unit square usually means the one with coordinates (0, 0), (1, 0), (1, 1), (0, 1) in the real plane, or 0, 1,  $1+i$ , and  $i$  in the COMPLEX PLANE.

see also HEILBRONN TRIANGLE PROBLEM, UNIT CIRCLE, UNIT DISK

### Unit Step

see HEAVISIDE STEP FUNCTION

### Unit Vector

A VECTOR of unit length. The unit vector  $\hat{\mathbf{v}}$  having the same direction as a given (nonzero) vector  $\mathbf{v}$  is defined by

$$\hat{\mathbf{v}} \equiv \frac{\mathbf{v}}{|\mathbf{v}|},$$

where  $|\mathbf{v}|$  denotes the NORM of  $\mathbf{v}$ , is the unit vector in the same direction as the (finite) VECTOR  $\mathbf{v}$ . A unit VECTOR in the  $\mathbf{x}_n$  direction is given by

$$\hat{\mathbf{x}}_n \equiv \frac{\frac{\partial \mathbf{r}}{\partial x_n}}{\left| \frac{\partial \mathbf{r}}{\partial x_n} \right|},$$

where  $\mathbf{r}$  is the RADIUS VECTOR.

see also NORM, RADIUS VECTOR, VECTOR

## Unital

A BLOCK DESIGN of the form  $(q^3 + 1, q + 1, 1)$ .

## Unitary Group

The unitary group  $U_n(q)$  is the set of  $n \times n$  UNITARY MATRICES.

see also LIE-TYPE GROUP, UNITARY MATRIX

### References

Wilson, R. A. "ATLAS of Finite Group Representation." <http://for.mat.bham.ac.uk/atlas#unit>.

## Unitary Matrix

A unitary matrix is a MATRIX  $U$  for which

$$U^\dagger = U^{-1}, \quad (1)$$

where  $\dagger$  denotes the ADJOINT OPERATOR. This guarantees that

$$U^\dagger U = 1. \quad (2)$$

Unitary matrices leave the length of a COMPLEX vector unchanged. The product of two unitary matrices is itself unitary. If  $U$  is unitary, then so is  $U^{-1}$ . A SIMILARITY TRANSFORMATION of a HERMITIAN MATRIX with a unitary matrix gives

$$\begin{aligned} (uau^{-1})^\dagger &= [(ua)(u^{-1})]^\dagger = (u^{-1})^\dagger(ua)^\dagger = (u^\dagger)^\dagger(a^\dagger u^\dagger) \\ &= uau^\dagger = uau^{-1}. \end{aligned} \quad (3)$$

For REAL MATRICES, HERMITIAN is the same as ORTHOGONAL. Unitary matrices are NORMAL MATRICES.

If  $M$  is a unitary matrix, then the PERMANENT

$$|\text{perm}(M)| \leq 1 \quad (4)$$

(Minc 1978, p. 25, Vardi 1991).

## Unitary Multiperfect Number

A number  $n$  which is an INTEGER multiple  $k$  of the SUM of its UNITARY DIVISORS  $\sigma^*(n)$  is called a unitary  $k$ -multiperfect number. There are no ODD unitary multiperfect numbers.

### References

Guy, R. K. "Unitary Perfect Numbers." §B3 in *Unsolved Problems in Number Theory, 2nd ed.* New York: Springer-Verlag, pp. 53–59, 1994.

## Unitary Multiplicative Character

A MULTIPLICATIVE CHARACTER is called unitary if it has ABSOLUTE VALUE 1 everywhere.

see also CHARACTER (MULTIPLICATIVE)

**Unitary Perfect Number**

A number  $n$  which is the sum of its UNITARY DIVISORS with the exception of  $n$  itself. There are no ODD unitary perfect numbers, and it has been conjectured that there are only a FINITE number of EVEN ones. The first few are 6, 60, 90, 87360, 146361946186458562560000, ... (Sloane's A002827).

- Guy, R. K. "Unitary Aliquot Sequences." §B8 in *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 63–65, 1994.

**Unitary Transformation**

A transformation of the form

$$A' = UAU^\dagger,$$

where  $\dagger$  denotes the ADJOINT OPERATOR.

see also ADJOINT OPERATOR, TRANSFORMATION

**Unitary Unimodular Group**

see SPECIAL UNITARY GROUP

**Unity**

The number 1. There are  $n$   $n$ th ROOTS OF UNITY, known as the DE MOIVRE NUMBERS.

see also 1, PRIMITIVE ROOT OF UNITY

**Univalent Function**

A function or transformation  $f$  in which  $f(z)$  does not overlap  $z$ .

**Univariate Function**

A FUNCTION of a single variable (e.g.,  $f(x)$ ,  $g(z)$ ,  $\theta(\xi)$ , etc.).

see also MULTIVARIATE FUNCTION

**Univariate Polynomial**

A POLYNOMIAL in a single variable. In common usage, univariate POLYNOMIALS are sometimes simply called "POLYNOMIALS."

see also POLYNOMIAL

**Universal Graph**

see COMPLETE GRAPH

**Universal Statement**

A universal statement  $S$  is a FORMULA whose FREE variables are all in the scope of universal quantifiers.

**Universal Turing Machine**

A TURING MACHINE which, by appropriate programming using a finite length of input tape, can act as any TURING MACHINE whatsoever.

see CHAITIN'S CONSTANT, HALTING PROBLEM, TURING MACHINE

References

- Penrose, R. *The Emperor's New Mind: Concerning Computers, Minds, and the Laws of Physics*. Oxford: Oxford University Press, pp. 51–57, 1989.

**Unknot**

A closed loop which is not KNOTTED. In the 1930s, by making use of REIDEMEISTER MOVES, Reidemeister first proved that KNOTS exist which are distinct from the unknot. He proved this by COLORING each part of a knot diagram with one of three colors.

The KNOT SUM of two unknots is another unknot.

The JONES POLYNOMIAL of the unknot is defined to give the normalization

$$V(t) = 1.$$

Haken (1961) devised an ALGORITHM to tell if a knot projection is the unknot. The ALGORITHM is so complicated, however, that it has never been implemented. Although it is not immediately obvious, the unknot is a PRIME KNOT.

see also COLORABLE, KNOT, KNOT THEORY, LINK, REIDEMEISTER MOVES, UNKNOTTING NUMBER

References

- Haken, W. "Theorie der Normalflächen." *Acta Math.* **105**, 245–375, 1961.

**Unknotting Number**

The smallest number of times a KNOT must be passed through itself to untie it. Lower bounds can be computed using relatively straightforward techniques, but it is in general difficult to determine exact values. Many unknotting numbers can be determined from a knot's SIGNATURE. A KNOT with unknotting number 1 is a PRIME KNOT (Scharlemann 1985). It is not always true that the unknotting number is achieved in a projection with the minimal number of crossings.

The following table is from Kirby (1997, pp. 88–89), with the values for  $10_{139}$  and  $10_{152}$  taken from Kawamura. The unknotting numbers for  $10_{154}$  and  $10_{161}$  can be found using MENASCO'S THEOREM (Stoimenow 1998).

**Untouchable Number**

An untouchable number is an INTEGER which is not the sum of the PROPER DIVISORS of any other number. The first few are 2, 5, 52, 88, 96, 120, 124, 146, ... (Sloane's A005114). Erdős has proven that there are infinitely many. It is thought that 5 is the only ODD untouchable number.

**Upper Bound**

see LEAST UPPER BOUND

**Upper Integral**

The limit of an UPPER SUM, when it exists, as the MESH SIZE approaches 0.

see also LOWER INTEGRAL, RIEMANN INTEGRAL, UPPER SUM

**Upper Limit**

Let the greatest term  $H$  of a SEQUENCE be a term which is greater than all but a finite number of the terms which are equal to  $H$ . Then  $H$  is called the upper limit of the SEQUENCE.

An upper limit of a SERIES

$$\text{upper } \lim_{n \rightarrow \infty} S_n = \overline{\lim}_{n \rightarrow \infty} S_n = k$$

is said to exist if, for every  $\epsilon > 0$ ,  $|S_n - k| < \epsilon$  for infinitely many values of  $n$  and if no number larger than  $k$  has this property.

see also LIMIT, LOWER LIMIT

## Utility Graph

The utility problem asks, “Can a PLANAR GRAPH be constructed from each of three nodes (‘house owners’) to each of three other nodes (‘wells’)?” The answer is no, and the proof can be effected using the JORDAN CURVE THEOREM, while a more general result encompassing this one is the KURATOWSKI REDUCTION THEOREM. The utility graph  $UG$  is the graph showing the relationships described above. It is identical to the THOMSEN GRAPH and, in the more formal parlance of GRAPH THEORY, is known as the COMPLETE BIPARTITE GRAPH  $K_{3,3}$ .

*see also* COMPLETE BIPARTITE GRAPH, KURATOWSKI REDUCTION THEOREM, PLANAR GRAPH, THOMSEN GRAPH

# V

## Valence

see VALENCY

## Valency

The number of EDGES at a GRAPH VERTEX.

## Valuation

A generalization of the  $p$ -ADIC NUMBERS first proposed by Kürschák in 1913. A valuation  $|\cdot|$  on a FIELD  $K$  is a FUNCTION from  $K$  to the REAL NUMBERS  $\mathbb{R}$  such that the following properties hold for all  $x, y \in K$ :

1.  $|x| \geq 0$ ,
2.  $|x| = 0$  IFF  $x = 0$ ,
3.  $|xy| = |x| |y|$ ,
4.  $|x| \leq 1$  IMPLIES  $|1+x| \leq C$  for some constant  $C \geq 1$  (independent of  $x$ ).

If (4) is satisfied for  $C = 2$ , then  $|\cdot|$  satisfies the TRIANGLE INEQUALITY,

$$4a. |x + y| \leq |x| + |y| \text{ for all } x, y \in K.$$

If (4) is satisfied for  $C = 1$  then  $|\cdot|$  satisfies the stronger TRIANGLE INEQUALITY

$$4b. |x + y| \leq \max(|x|, |y|).$$

The simplest valuation is the ABSOLUTE VALUE for REAL NUMBERS. A valuation satisfying (4b) is called non-ARCHIMEDEAN VALUATION; otherwise, it is called ARCHIMEDEAN.

If  $|\cdot|_1$  is a valuation on  $K$  and  $\lambda \geq 1$ , then we can define a new valuation  $|\cdot|_2$  by

$$|x|_2 = |x|_1^\lambda. \quad (1)$$

This does indeed give a valuation, but possibly with a different constant  $C$  in AXIOM 4. If two valuations are related in this way, they are said to be equivalent, and this gives an equivalence relation on the collection of all valuations on  $K$ . Any valuation is equivalent to one which satisfies the triangle inequality (4a). In view of this, we need only to study valuations satisfying (4a), and we often view axioms (4) and (4a) as interchangeable (although this is not strictly true).

If two valuations are equivalent, then they are both non-ARCHIMEDEAN or both ARCHIMEDEAN.  $\mathbb{Q}$ ,  $\mathbb{R}$ , and  $\mathbb{C}$  with the usual Euclidean norms are Archimedean valued fields. For any PRIME  $p$ , the  $p$ -ADIC NUMBERS  $\mathbb{Q}_p$  with the  $p$ -adic valuation  $|\cdot|_p$  is a non-Archimedean valued field.

If  $K$  is any FIELD, we can define the trivial valuation on  $K$  by  $|x| = 1$  for all  $x \neq 0$  and  $|0| = 0$ , which is a non-Archimedean valuation. If  $K$  is a FINITE FIELD, then the only possible valuation over  $K$  is the trivial one. It can be shown that any valuation on  $\mathbb{Q}$  is equivalent

to one of the following: the trivial valuation, Euclidean absolute norm  $|\cdot|$ , or  $p$ -adic valuation  $|\cdot|_p$ .

The equivalence of any nontrivial valuation of  $\mathbb{Q}$  to either the usual ABSOLUTE VALUE or to a  $p$ -ADIC NUMBER absolute value was proved by Ostrowski (1935). Equivalent valuations give rise to the same topology. Conversely, if two valuations have the same topology, then they are equivalent. A stronger result is the following: Let  $|\cdot|_1, |\cdot|_2, \dots, |\cdot|_k$  be valuations over  $K$  which are pairwise inequivalent and let  $a_1, a_2, \dots, a_k$  be elements of  $K$ . Then there exists an infinite sequence  $(x_1, x_2, \dots)$  of elements of  $K$  such that

$$\lim_{n \rightarrow \infty \text{ w.r.t. } |\cdot|_1} x_n = a_1 \quad (2)$$

$$\lim_{n \rightarrow \infty \text{ w.r.t. } |\cdot|_2} x_n = a_2, \quad (3)$$

etc. This says that inequivalent valuations are, in some sense, completely independent of each other. For example, consider the rationals  $\mathbb{Q}$  with the 3-adic and 5-adic valuations  $|\cdot|_3$  and  $|\cdot|_5$ , and consider the sequence of numbers given by

$$x_n = \frac{43 \cdot 5^n + 92 \cdot 3^n}{3^n + 5^n}. \quad (4)$$

Then  $x_n \rightarrow 43$  as  $n \rightarrow \infty$  with respect to  $|\cdot|_3$ , but  $x_n \rightarrow 92$  as  $n \rightarrow \infty$  with respect to  $|\cdot|_5$ , illustrating that a sequence of numbers can tend to two different limits under two different valuations.

A discrete valuation is a valuation for which the VALUATION GROUP is a discrete subset of the REAL NUMBERS  $\mathbb{R}$ . Equivalently, a valuation (on a FIELD  $K$ ) is discrete if there exists a REAL NUMBER  $\epsilon > 0$  such that

$$|x| \in (1 - \epsilon, 1 + \epsilon) \Rightarrow |x| = 1 \text{ for all } x \in K. \quad (5)$$

The  $p$ -adic valuation on  $\mathbb{Q}$  is discrete, but the ordinary absolute valuation is not.

If  $|\cdot|$  is a valuation on  $K$ , then it induces a metric

$$d(x, y) = |x - y| \quad (6)$$

on  $K$ , which in turn induces a TOPOLOGY on  $K$ . If  $|\cdot|$  satisfies (4b) then the metric is an ULTRAMETRIC. We say that  $(K, |\cdot|)$  is a complete valued field if the METRIC SPACE is complete.

**Valuation Group**

Let  $(K, |\cdot|)$  be a valuated field. The valuation group  $G$  is defined to be the set

$$G = \{|x| : x \in K, x \neq 0\},$$

with the group operation being multiplication. It is a SUBGROUP of the POSITIVE REAL NUMBERS, under multiplication.

**Valuation Ring**

Let  $(K, |\cdot|)$  be a non-Archimedean valuated field. Its valuation ring  $R$  is defined to be

$$R = \{x \in K : |x| \leq 1\}.$$

The valuation ring has maximal IDEAL

$$M = \{x \in K : |x| < 1\},$$

and the field  $R/M$  is called the residue field, class field, or field of digits. For example, if  $K = \mathbb{Q}_p$  ( $p$ -adic numbers), then  $R = \mathbb{Z}_p$  ( $p$ -adic integers),  $M = p\mathbb{Z}_p$  ( $p$ -adic integers congruent to 0 mod  $p$ ), and  $R/M = \text{GF}(p)$ , the FINITE FIELD of order  $p$ .

**Valuation Theory**

The study of VALUATIONS which simplifies class field theory and the theory of algebraic function fields.

see also VALUATION

**References**

**Value**

The quantity which a FUNCTION  $f$  takes upon application to a given quantity.

see also VALUE (GAME)

**Value (Game)**

The solution to a GAME in GAME THEORY. When a SADDLE POINT is present

$$\min_{i \leq m} \min_{j \leq n} a_{ij} = \min_{j \leq n} \max_{i \leq m} a_{ij} \equiv v,$$

and  $v$  is the value for pure strategies.

see also ABSOLUTE VALUE, GAME THEORY, MINIMAX THEOREM, VALUATION

**Vampire Number**

A number  $v = xy$  with an EVEN number  $n$  of DIGITS formed by multiplying a pair of  $n/2$ -DIGIT numbers (where the DIGITS are taken from the original number in any order)  $x$  and  $y$  together. Pairs of trailing zeros are not allowed. If  $v$  is a vampire number, then  $x$  and  $y$  are called its "fangs." Examples of vampire numbers include

$$1260 = 21 \times 60$$

$$1395 = 15 \times 93$$

$$1435 = 35 \times 41$$

$$1530 = 30 \times 51$$

$$1827 = 21 \times 87$$

$$2187 = 27 \times 81$$

$$6880 = 80 \times 86$$

(Sloane's A014575). There are seven 4-digit vampires, 155 6-digit vampires, and 3382 8-digit vampires. General formulas can be constructed for special classes of vampires, such as the fangs

$$\begin{aligned} x &= 25 \cdot 10^k + 1 \\ y &= 100(10^{k+1} + 52)/25, \end{aligned}$$

giving the vampire

$$\begin{aligned} v &= xy = (10^{k+1} + 52)10^{k+2} + 100(10^{k+1} + 52)/25 \\ &= x^* \cdot 10^{k+2} + t \\ &= 8(26 + 5 \cdot 10^k)(1 + 25 \cdot 10^k), \end{aligned}$$

where  $x^*$  denotes  $x$  with the DIGITS reversed (Roushe and Rogers).

Pickover (1995) also defines pseudovampire numbers, in which the multiplicands have different number of digits.

van der Grinten Projection

A MAP PROJECTION given by the transformation

$$x = \operatorname{sgn}(\lambda - \lambda_0) \times \frac{\pi |A(G - P^2) - \sqrt{A^2(G - P^2)^2 - (P^2 + A^2)(G^2 - P^2)}|}{P^2 + A^2} \quad (1)$$

$$y = \operatorname{sgn}(\phi) \frac{\pi |PQ - A\sqrt{(A^2 + 1)(P^2 + A^2) - Q^2}|}{P^2 + A^2}, \quad (2)$$

where

$$A = \frac{1}{2} \left| \frac{\pi}{\lambda - \lambda_0} - \frac{\lambda - \lambda_0}{\pi} \right| \quad (3)$$

$$G = \frac{\cos \theta}{\sin \theta + \cos \theta - 1} \quad (4)$$

$$P = G \left( \frac{2}{\sin \theta} - 1 \right) \quad (5)$$

$$\theta = \sin^{-1} \left| \frac{2\phi}{\pi} \right| \quad (6)$$

$$Q = A^2 + G. \quad (7)$$

The inverse FORMULAS are

$$\phi = \operatorname{sgn}(y) \pi \left[ -m_1 \cos(\theta_1 + \frac{1}{3}\pi) - \frac{c_2}{3c_3} \right] \quad (8)$$

$$\lambda = \frac{\pi |X^2 + Y^2 - 1 + \sqrt{1 + 2(X^2 - Y^2) + (X^2 + Y^2)^2}|}{2X} + \lambda_0, \quad (9)$$

where

$$X = \frac{x}{\pi} \quad (10)$$

$$Y = \frac{y}{\pi} \quad (11)$$

$$c_1 = -|Y|(1 + X^2 + Y^2) \quad (12)$$

$$c_2 = c_1 - 2Y^2 + X^2 \quad (13)$$

$$c_3 = -2c_1 + 1 + 2Y^2 + (X^2 + Y^2)^2 \quad (14)$$

$$d = \frac{Y^2}{c_3} + \frac{1}{27} \left( \frac{2c_2^3}{c_3^3} - \frac{9c_1c_2}{c_3^2} \right) \quad (15)$$

$$a_1 = \frac{1}{c_3} \left( c_1 - \frac{c_2^2}{3c_3} \right) \quad (16)$$

$$m_1 = 2\sqrt{-\frac{1}{3}a_1} \quad (17)$$

$$\theta_1 = \frac{1}{3} \cos^{-1} \left( \frac{3d}{a_1m_1} \right). \quad (18)$$

**Vandermonde Theorem**

A special case of GAUSS'S THEOREM with  $a$  a NEGATIVE INTEGER  $-n$ :

$${}_2F_1(-n, b; c; 1) = \frac{(c-b)_n}{(c)_n},$$

where  ${}_2F_1(a, b; c; z)$  is a HYPERGEOMETRIC FUNCTION and  $(a)_n$  is a POCHHAMMER SYMBOL (Bailey 1935, p. 3).

see also GAUSS'S THEOREM

**References**

Bailey, W. N. *Generalised Hypergeometric Series*. Cambridge, England: Cambridge University Press, 1935.

**Vandiver's Criteria**

Let  $p$  be a IRREGULAR PRIME, and let  $P = rp + 1$  be a PRIME with  $P < p^2 - p$ . Also let  $t$  be an INTEGER such that  $t^3 \not\equiv 1 \pmod{P}$ . For an IRREGULAR PAIR  $(p, 2k)$ , form the product

$$Q_{2k} = t^{-rd/2} \prod_{b=1}^m (t^{rb} - 1)^{b^{p-1-2k}},$$

where

$$m = \frac{1}{2}(p-1) \\ d = \sum_{n=1}^m n^{p-2k}.$$

If  $Q_{2k} \not\equiv 1 \pmod{P}$  for all such IRREGULAR PAIRS, then FERMAT'S LAST THEOREM holds for exponent  $p$ .

## Varga's Constant

$$V \equiv \frac{1}{\Lambda} = 9.2890254919 \dots,$$

where  $\Lambda$  is the ONE-NINTH CONSTANT.

see also ONE-NINTH CONSTANT

## Variance

For  $N$  samples of a variate having a distribution with *known* MEAN  $\mu$ , the "population variance" (usually called "variance" for short, although the word "population" should be added when needed to distinguish it from the SAMPLE VARIANCE) is defined by

$$\begin{aligned} \text{var}(x) &\equiv \frac{1}{N} \sum (x - \mu)^2 = \langle x^2 - 2\mu x + \mu^2 \rangle \\ &= \langle x^2 \rangle - \langle 2\mu x \rangle + \langle \mu^2 \rangle \\ &= \langle x^2 \rangle - 2\mu \langle x \rangle + \mu^2, \end{aligned} \quad (1)$$

where

$$\langle x \rangle \equiv \frac{1}{N} \sum_{i=1}^N x_i. \quad (2)$$

But since  $\langle x \rangle$  is an UNBIASED ESTIMATOR for the MEAN

$$\mu \equiv \langle x \rangle, \quad (3)$$

it follows that the variance

$$\sigma^2 \equiv \text{var}(x) = \langle x^2 \rangle - \mu^2. \quad (4)$$

The population STANDARD DEVIATION is then defined as

$$\sigma \equiv \sqrt{\text{var}(x)} = \sqrt{\langle x^2 \rangle - \mu^2}. \quad (5)$$

A useful identity involving the variance is

$$\text{var}(f(x) + g(x)) = \text{var}(f(x)) + \text{var}(g(x)). \quad (6)$$

Therefore,

$$\begin{aligned} \text{var}(ax + b) &= \langle [(ax + b) - \langle ax + b \rangle]^2 \rangle \\ &= \langle (ax + b - a\langle x \rangle - b)^2 \rangle \\ &= \langle (ax - a\mu)^2 \rangle = \langle a^2(x - \mu)^2 \rangle \\ &= a^2 \langle (x - \mu)^2 \rangle = a^2 \text{var}(x) \end{aligned} \quad (7)$$

$$\text{var}(b) = 0. \quad (8)$$

If the population MEAN is not known, using the sample mean  $\bar{x}$  instead of the population mean  $\mu$  to compute

$$s^2 \equiv \hat{\sigma}_N^2 \equiv \frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^2 \quad (9)$$

gives a BIASED ESTIMATOR of the population variance. In such cases, it is appropriate to use a STUDENT'S  $t$ -DISTRIBUTION instead of a GAUSSIAN DISTRIBUTION.

However, it turns out (as discussed below) that an UNBIASED ESTIMATOR for the population variance is given by

$$s'^2 \equiv \hat{\sigma}_N'^2 \equiv \frac{1}{N-1} \sum_{i=1}^N (x_i - \bar{x})^2. \quad (10)$$

The MEAN and VARIANCE of the sample standard deviation for a distribution with population mean  $\mu$  and VARIANCE are

$$\mu_{s_N^2} = \frac{N-1}{N} s^2 \quad (11)$$

$$\sigma_{s_N^2}^2 = \frac{N-1}{N^3} [(N-1)\mu_4 - (N-3)\mu_2^2]. \quad (12)$$

The quantity  $Ns_N^2/\sigma^2$  has a CHI-SQUARED DISTRIBUTION.

For multiple variables, the variance is given using the definition of COVARIANCE,

$$\begin{aligned} \text{var} \left( \sum_{i=1}^n x_i \right) &= \text{cov} \left( \sum_{i=1}^n x_i, \sum_{j=1}^m x_j \right) \\ &= \sum_{i=1}^n \sum_{j=1}^m \text{cov}(x_i, x_j) \\ &= \sum_{i=1}^n \sum_{\substack{j=1 \\ j \neq i}}^m \text{cov}(x_i, x_j) + \sum_{i=1}^n \sum_{\substack{j=1 \\ j=i}}^m \text{cov}(x_i, x_j) \\ &= \sum_{i=1}^n \text{cov}(x_i, x_i) + \sum_{i=1}^n \sum_{\substack{j=1 \\ j \neq i}}^m \text{cov}(x_i, x_j) \\ &= \sum_{i=1}^n \text{var}(x_i) + 2 \sum_{i=1}^n \sum_{j=i+1}^m \text{cov}(x_i, x_j). \end{aligned} \quad (13)$$

A linear sum has a similar form:

$$\begin{aligned} \text{var} \left( \sum_{i=1}^n a_i x_i \right) &= \text{cov} \left( \sum_{i=1}^n a_i x_i, \sum_{j=1}^m a_j x_j \right) \\ &= \sum_{i=1}^n \sum_{j=1}^m a_i a_j \text{cov}(x_i, x_j) \\ &= \sum_{i=1}^n a_i^2 \text{var}(x_i) + 2 \sum_{i=1}^n \sum_{j=i+1}^m a_i a_j \text{cov}(x_i, x_j). \end{aligned} \quad (14)$$

These equations can be expressed using the COVARIANCE MATRIX.

To estimate the population VARIANCE from a sample of  $N$  elements with a priori *unknown* MEAN (i.e., the MEAN is estimated from the sample itself), we need an

UNBIASED ESTIMATOR for  $\sigma$ . This is given by the  $k$ -STATISTIC  $k_2$ , where

$$k_2 = \frac{N}{N-1} m_2 \quad (15)$$

and  $m_2 \equiv s^2$  is the SAMPLE VARIANCE

$$s^2 \equiv \frac{1}{N} \sum_{i=1}^N (x_i - \bar{x})^2. \quad (16)$$

Note that some authors prefer the definition

$$s'^2 \equiv \frac{1}{N-1} \sum_{i=1}^N (x_i - \bar{x})^2, \quad (17)$$

since this makes the sample variance an UNBIASED ESTIMATOR for the population variance.

When computing numerically, the MEAN must be computed before  $s^2$  can be determined. This requires storing the set of sample values. It is possible to calculate  $s'^2$  using a recursion relationship involving only the last sample as follows. Here, use  $\mu_j$  to denote  $\mu$  calculated from the first  $j$  samples (*not* the  $j$ th MOMENT)

$$\mu_j \equiv \frac{\sum_{i=1}^j x_i}{j}, \quad (18)$$

and  $s_j^2$  denotes the value for the sample variance  $s'^2$  calculated from the first  $j$  samples. The first few values calculated for the MEAN are

$$\mu_1 = x_1 \quad (19)$$

$$\mu_2 = \frac{1 \cdot \mu_1 + x_2}{2} \quad (20)$$

$$\mu_3 = \frac{2\mu_2 + x_3}{3}. \quad (21)$$

Therefore, for  $j = 2, 3$  it is true that

$$\mu_j = \frac{(j-1)\mu_{j-1} + x_j}{j}. \quad (22)$$

Therefore, by induction,

$$\begin{aligned} \mu_{j+1} &= \frac{[(j+1)-1]\mu_{(j+1)-1} + x_{j+1}}{j+1} \\ &= \frac{j\mu_j + x_{j+1}}{j+1} \end{aligned} \quad (23)$$

$$\mu_{j+1}(j+1) = (j+1)\mu_j + (x_{j+1} - \mu_j) \quad (24)$$

$$\mu_{j+1} = \mu_j + \frac{x_{j+1} - \mu_j}{j+1}, \quad (25)$$

and

$$s_j^2 = \frac{\sum_{i=1}^j (x_i - \mu_j)^2}{j-1} \quad (26)$$

for  $j \geq 2$ , so

$$\begin{aligned} j s_{j+1}^2 &= j \frac{\sum_{i=1}^{j+1} (x_i - \mu_{j+1})^2}{j} = \sum_{i=1}^{j+1} (x_i - \mu_{j+1})^2 \\ &= \sum_{i=1}^{j+1} [(x_i - \mu_j) + (\mu_j - \mu_{j+1})]^2 \\ &= \sum_{i=1}^{j+1} (x_i - \mu_j)^2 + \sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})^2 \\ &\quad + 2 \sum_{i=1}^{j+1} (x_i - \mu_j)(\mu_j - \mu_{j+1}). \end{aligned} \quad (27)$$

Working on the first term,

$$\begin{aligned} \sum_{i=1}^{j+1} (x_i - \mu_j)^2 &= \sum_{i=1}^j (x_i - \mu_j)^2 + (x_{j+1} - \mu_j)^2 \\ &= (j-1)s_j^2 + (x_{j+1} - \mu_j)^2. \end{aligned} \quad (28)$$

Use (24) to write

$$x_{j+1} - \mu_j = (j+1)(\mu_{j+1} - \mu_j), \quad (29)$$

so

$$\sum_{i=1}^{j+1} (x_i - \mu_j)^2 = (j-1)s_j^2 + (j+1)^2(\mu_{j+1} - \mu_j)^2. \quad (30)$$

Now work on the second term in (27),

$$\sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})^2 = (j+1)(\mu_j - \mu_{j+1})^2. \quad (31)$$

Considering the third term in (27),

$$\begin{aligned} \sum_{i=1}^{j+1} (x_i - \mu_j)(\mu_j - \mu_{j+1}) &= (\mu_j - \mu_{j+1}) \sum_{i=1}^{j+1} (x_i - \mu_j) \\ &= (\mu_j - \mu_{j+1}) \left[ \sum_{i=1}^j (x_i - \mu_j) + (x_{j+1} - \mu_j) \right] \\ &= (\mu_j - \mu_{j+1}) \left( x_{j+1} - \mu_j - j\mu_j + \sum_{i=1}^j x_i \right). \end{aligned} \quad (32)$$

But

$$\sum_{i=1}^j x_i = j\mu_j, \quad (33)$$

so

$$\begin{aligned} \sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})(x_{j+1} - \mu_j) &= \sum_{i=1}^{j+1} (\mu_j - \mu_{j+1})(j+1)(\mu_{j+1} - \mu_j) \\ &= -(j+1)(\mu_j - \mu_{j+1})^2. \end{aligned} \quad (34)$$

Plugging (30), (31), and (34) into (27),

$$\begin{aligned} js_{j+1}^2 &= [(j-1)s_j^2 + (j+1)^2(\mu_{j+1} - \mu_j)^2] \\ &\quad + [(j+1)(\mu_j - \mu_{j+1}) + 2[-(j+1)(\mu_j - \mu_{j+1})]] \\ &= (j-1)s_j^2 + (j+1)^2(\mu_{j+1} - \mu_j)^2 \\ &\quad - (j+1)(\mu_j - \mu_{j+1})^2 \\ &= (j-1)s_j^2 + (j+1)[(j+1)-1](\mu_{j+1} - \mu_j)^2 \\ &= (j-1)s_j^2 + j(j+1)(\mu_{j+1} - \mu_j)^2, \end{aligned} \quad (35)$$

so

$$s_{j+1}^2 = \left(1 - \frac{1}{j}\right) s_j^2 + (j+1)(\mu_{j+1} - \mu_j)^2. \quad (36)$$

To find the variance of  $s^2$  itself, remember that

$$\text{var}(s^2) \equiv \langle s^4 \rangle - \langle s^2 \rangle^2, \quad (37)$$

and

$$\langle s^2 \rangle = \frac{N-1}{N} \mu_2. \quad (38)$$

Now find  $\langle s^4 \rangle$ .

$$\begin{aligned} \langle s^4 \rangle &= \langle (s^2)^2 \rangle = \langle ((\sum x_i^2) - \langle \sum x_i^2 \rangle)^2 \rangle \\ &= \left\langle \left[ \frac{1}{N} \sum x_i^2 - \left( \frac{1}{N} \sum x_i \right)^2 \right]^2 \right\rangle \\ &= \frac{1}{N^2} \left\langle \left( \sum x_i \right)^2 \right\rangle - \frac{2}{N^3} \left\langle \sum x_i^2 \left( \sum x_i \right)^2 \right\rangle \\ &\quad + \frac{1}{N^4} \left\langle \left( \sum x_i \right)^4 \right\rangle. \end{aligned} \quad (39)$$

Working on the first term of (39),

$$\begin{aligned} \left\langle \left( \sum x_i^2 \right)^2 \right\rangle &= \left\langle \sum x_i^4 + \sum x_i^2 x_j^2 \right\rangle \\ &= \left\langle \sum x_i^4 \right\rangle + \left\langle \sum x_i^2 x_j^2 \right\rangle \\ &= N \langle x_i^4 \rangle + N(N-1) \langle x_i^2 \rangle \langle x_j^2 \rangle \\ &= N\mu'_4 + N(N-1)\mu_2'^2. \end{aligned} \quad (40)$$

The second term of (39) is known from  $k$ -STATISTICS,

$$\left\langle \sum x_i^2 \left( \sum x_j \right)^2 \right\rangle = N\mu'_4 + N(N-1)\mu_2'^2, \quad (41)$$

as is the third term,

$$\begin{aligned} \left\langle \left( \sum x_i \right)^4 \right\rangle &= N \left\langle \sum x_i^4 \right\rangle + 3N(N-1) \left\langle \sum x_i^2 x_j^2 \right\rangle \\ &= N\mu'_4 + 3N(N-1)\mu_2'^2. \end{aligned} \quad (42)$$

Combining (39)-(42) gives

$$\begin{aligned} \langle s^4 \rangle &= \frac{1}{N^2} [N\mu'_4 + N(N-1)\mu_2'^2] \\ &\quad - \frac{2}{N^3} [N\mu'_4 + N(N-1)\mu_2'^2] \\ &\quad + \frac{1}{N^4} [N\mu'_4 + 3N(N-1)\mu_2'^2] \\ &= \left( \frac{1}{N} - \frac{2}{N^2} + \frac{1}{N^3} \right) \mu'_4 \\ &\quad + \left[ \frac{N-1}{N} - \frac{2(N-1)}{N^2} + \frac{3(N-1)}{N^3} \right] \mu_2'^2 \\ &= \left( \frac{N^2 - 2N + 1}{N^3} \right) \mu'_4 \\ &\quad + \frac{(N-1)(N^2 - 2N + 3)}{N^3} \mu_2'^2 \\ &= \frac{(N-1)[(N-1)\mu'_4 + (N^2 - 2N + 3)\mu_2'^2]}{N^3}, \end{aligned} \quad (43)$$

so plugging in (38) and (43) gives

$$\begin{aligned} \text{var}(s^2) &= \langle s^4 \rangle - \langle s^2 \rangle^2 \\ &= \frac{(N-1)[(N-1)\mu'_4 + (N^2 - 2N + 3)\mu_2'^2]}{N^3} \\ &\quad - \frac{(N-1)^2 N}{N^3} \mu_2'^2 \\ &= \frac{N-1}{N^3} \{ (N-1)\mu'_4 + [(N^2 - 2N + 3) \\ &\quad - N(N-1)]\mu_2'^2 \} \\ &= \frac{(N-1)[(N-1)\mu'_4 - (N-3)\mu_2'^2]}{N^3}. \end{aligned} \quad (44)$$

Student calculated the SKEWNESS and KURTOSIS of the distribution of  $s^2$  as

$$\gamma_1 = \sqrt{\frac{8}{N-1}} \quad (45)$$

$$\gamma_2 = \frac{12}{N-1} \quad (46)$$

and conjectured that the true distribution is PEARSON TYPE III DISTRIBUTION

$$f(s^2) = C(s^2)^{(N-3)/2} e^{-Ns^2/2\sigma^2}, \quad (47)$$

where

$$\sigma^2 = \frac{Ns^2}{N-1} \quad (48)$$

$$C = \frac{\left(\frac{N}{2\sigma^2}\right)^{(N-1)/2}}{\Gamma\left(\frac{N-1}{2}\right)}. \quad (49)$$

This was proven by R. A. Fisher.

The distribution of  $s$  itself is given by

$$f(s) = 2 \frac{\left(\frac{N}{2\sigma^2}\right)^{(N-1)/2}}{\Gamma\left(\frac{N-1}{2}\right)} e^{-ns^2/2\sigma^2} s^{N-2} \quad (50)$$

$$\langle s \rangle = \sqrt{\frac{2}{N}} \frac{\Gamma\left(\frac{N}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)} \sigma \equiv b(N)\sigma, \quad (51)$$

where

$$b(N) \equiv \sqrt{\frac{2}{N}} \frac{\Gamma\left(\frac{N}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)}. \quad (52)$$

The MOMENTS are given by

$$\mu_r = \left(\frac{2}{N}\right)^{r/2} \frac{\Gamma\left(\frac{N-1+r}{2}\right)}{\Gamma\left(\frac{N-1}{2}\right)} \sigma^r, \quad (53)$$

and the variance is

$$\begin{aligned} \text{var}(s) &= \nu_2 - \nu_1^2 = \frac{N-1}{N} \sigma^2 - [b(N)\sigma]^2 \\ &= \frac{1}{N} \left[ N-1 - \frac{2\Gamma^2\left(\frac{N}{2}\right)}{\Gamma^2\left(\frac{N-1}{2}\right)} \sigma^2 \right]. \end{aligned} \quad (54)$$

An UNBIASED ESTIMATOR of  $\sigma$  is  $s/b(N)$ . Romanovsky showed that

$$b(N) = 1 - \frac{3}{4N} - \frac{7}{32N^2} - \frac{139}{51849N^3} + \dots \quad (55)$$

### Variate

A RANDOM VARIABLE in statistics.

### Variation

The  $\Delta$ -variation is a variation in which the varied path over which an integral is evaluated may end at different times than the correct path, and there may be variation in the coordinates at the endpoints.

The  $\delta$ -variation is a variation in which the varied path in configuration space terminates at the endpoints representing the system configuration at the same time  $t_1$  and  $t_2$  as the correct path; i.e., the varied path always returns to the same endpoints in configuration space, so

$$\delta q_i(t_1) = \delta q_i(t_2) = 0.$$

see also CALCULUS OF VARIATIONS, VARIATION OF ARGUMENT, VARIATION OF PARAMETERS

### Variation of Argument

Let  $[\arg f(z)]$  denote the change in argument of a function  $f(z)$  around a closed loop  $\gamma$ . Also let  $N$  denote the number of ROOTS of  $f(z)$  in  $\gamma$  and  $P$  denote the number of POLES of  $f(z)$  in  $\gamma$ . Then

$$[\arg f(z)] = \frac{1}{2\pi}(N - P). \quad (1)$$

To find  $[\arg f(z)]$  in a given region  $R$ , break  $R$  into paths and find  $[\arg f(z)]$  for each path. On a circular ARC

$$z = Re^{i\theta}, \quad (2)$$

let  $f(z)$  be a POLYNOMIAL  $P(z)$  of degree  $n$ . Then

$$\begin{aligned} [\arg P(z)] &= \left[ \arg \left( z^n \frac{P(z)}{z^n} \right) \right] \\ &= [\arg z^n] + \left[ \arg \left( \frac{P(z)}{z^n} \right) \right]. \end{aligned} \quad (3)$$

Plugging in  $z = Re^{i\theta}$  gives

$$[\arg P(z)] = [\arg Re^{i\theta n}] + \left[ \arg \frac{P(Re^{i\theta})}{Re^{i\theta n}} \right] \quad (4)$$

$$\lim_{R \rightarrow \infty} \frac{P(Re^{i\theta})}{Re^{i\theta n}} = [\text{constant}], \quad (5)$$

so

$$\left[ \frac{P(Re^{i\theta})}{Re^{i\theta n}} \right] = 0, \quad (6)$$

and

$$[\arg P(z)] = [\arg e^{i\theta n}] = n(\theta_2 - \theta_1). \quad (7)$$

For a REAL segment  $z = x$ ,

$$[\arg f(x)] = \tan^{-1} \left[ \frac{0}{f(x)} \right] = 0. \quad (8)$$

For an IMAGINARY segment  $z = iy$ ,

$$[\arg f(iy)] = \left\{ \tan^{-1} \frac{\Im[P(iy)]}{\Re[P(iy)]} \right\}_{\theta_1}^{\theta_2}. \quad (9)$$

Note that the ARGUMENT must change continuously, so "jumps" occur across inverse tangent asymptotes.

### Variation Coefficient

If  $s_x$  is the STANDARD DEVIATION of a set of samples  $x_i$  and  $\bar{x}$  its MEAN, then

$$V \equiv \frac{s_x}{\bar{x}}.$$

### Variation of Parameters

For a second-order ORDINARY DIFFERENTIAL EQUATION,

$$y'' + p(x)y' + q(x)y = g(x). \quad (1)$$

Assume that linearly independent solutions  $y_1(x)$  and  $y_2(x)$  are known. Find  $v_1$  and  $v_2$  such that

$$y^*(x) = v_1(x)y_1(x) + v_2(x)y_2(x) \quad (2)$$

$$y^{*'}(x) = (v_1' + v_2'y_2) + (v_1y_1' + v_2y_2'). \quad (3)$$

Now, impose the additional condition that

$$v_1'y_1 + v_2'y_2 = 0 \quad (4)$$

so that

$$y^{*'}(x) = (v_1y_1' + v_2y_2') \quad (5)$$

$$y^{*''}(x) = v_1'y_1' + v_2'y_2' + v_1y_1'' + v_2y_2''. \quad (6)$$

Plug  $y^*$ ,  $y^{*'}$ , and  $y^{*''}$  back into the original equation to obtain

$$v_1(y_1'' + py_1' + qy_1) + v_2(y_2'' + py_2' + qy_2) + v_1'y_1' + v_2'y_2' = g(x) \quad (7)$$

$$v_1'y_1' + v_2'y_2' = g(x). \quad (8)$$

Therefore,

$$v_1'y_1 + v_2'y_2 = 0 \quad (9)$$

$$v_1'y_1' + v_2'y_2' = g(x). \quad (10)$$

Generalizing to an  $n$ th degree ODE, let  $y_1, \dots, y_n$  be the solutions to the homogeneous ODE and let  $v_1'(x), \dots, v_n'(x)$  be chosen such that

$$\begin{cases} y_1v_1' + y_2v_2' + \dots + y_nv_n' = 0 \\ y_1'y_1' + y_2'y_2' + \dots + y_n'y_n' = 0 \\ \vdots \\ y_1^{(n-1)}v_1' + y_2^{(n-1)}v_2' + \dots + y_n^{(n-1)}v_n' = g(x). \end{cases} \quad (11)$$

Then the particular solution is

$$y^*(x) = v_1(x)y_1(x) + \dots + v_n(x)y_n(x). \quad (12)$$

### Variety

### Varignon Parallelogram

The figure formed when the BIMEDIANS (MIDPOINTS of the sides) of a convex QUADRILATERAL are joined. VARIGNON'S THEOREM demonstrated that this figure is a PARALLELOGRAM. The center of the Varignon parallelogram is the CENTROID if four point masses are placed on the VERTICES of the QUADRILATERAL.

see also MIDPOINT, PARALLELOGRAM, QUADRILATERAL, VARIGNON'S THEOREM

### Varignon's Theorem

The figure formed when the BIMEDIANS (MIDPOINTS of the sides) of a convex QUADRILATERAL are joined in order is a PARALLELOGRAM. Equivalently, the BIMEDIANS bisect each other. The AREA of this VARIGNON PARALLELOGRAM is half that of the QUADRILATERAL. The PERIMETER is equal to the sum of the diagonals of the original QUADRILATERAL.

see also BIMEDIAN, MIDPOINT, QUADRILATERAL, VARIGNON PARALLELOGRAM

### Vassiliev Polynomial

Vassiliev (1990) introduced a radically new way of looking at KNOTS by considering a multidimensional space in which each point represents a possible 3-D knot configuration. If two KNOTS are equivalent, a path then exists in this space from one to the other. The paths can be associated with polynomial invariants.

Birman and Lin (1993) subsequently found a way to translate this scheme into a set of rules and list of potential starting points, which makes analysis of Vassiliev polynomials much simpler. Bar-Natan (1995) and Birman and Lin (1993) proved that JONES POLYNOMIALS and several related expressions are directly connected (Peterson 1992). In fact, substituting the POWER series for  $e^x$  as the variable in the JONES POLYNOMIAL yields a POWER SERIES whose COEFFICIENTS are Vassiliev polynomials (Birman and Lin 1993). Bar-Natan (1995) also discovered a link with Feynman diagrams (Peterson 1992).

### Vault

Let a vault consist of two equal half-CYLINDERS of length and diameter  $2a$  which intersect at RIGHT ANGLES so that the lines of their intersections (the "groins") terminate in the VERTICES of a SQUARE. Then the SURFACE AREA of the vault is given by

$$A = 4(\pi - 2)a^2.$$

### Vector

A vector is a set of numbers  $A_0, \dots, A_n$  that transform as

$$A'_i = a_{ij}A_j. \quad (1)$$

This makes a vector a TENSOR of RANK 1. Vectors are invariant under TRANSLATION, and they reverse sign upon inversion.

A vector is uniquely specified by giving its DIVERGENCE and CURL within a region and its normal component over the boundary, a result known as HELMHOLTZ'S THEOREM (Arfken 1985, p. 79). A vector from a point  $A$  to a point  $B$  is denoted  $\overrightarrow{AB}$ , and a vector  $v$  may be denoted  $\vec{v}$ , or more commonly,  $\mathbf{v}$ .

A vector with unit length is called a UNIT VECTOR and is denoted with a HAT. An arbitrary vector may be converted to a UNIT VECTOR by dividing by its NORM, i.e.,

$$\hat{\mathbf{v}} \equiv \frac{\mathbf{v}}{|\mathbf{v}|}. \quad (2)$$

Let  $\hat{\mathbf{n}}$  be the UNIT VECTOR defined by

$$\hat{\mathbf{n}} \equiv \begin{bmatrix} \cos \theta \sin \phi \\ \sin \theta \sin \phi \\ \cos \phi \end{bmatrix}. \quad (3)$$

Then the vectors  $\hat{\mathbf{n}}$ ,  $\mathbf{a}$ ,  $\mathbf{b}$ ,  $\mathbf{c}$ ,  $\mathbf{d}$  satisfy the identities

$$\begin{aligned} \langle n_x \rangle &= \int_0^{2\pi} \int_0^\pi (\cos \theta \sin \phi) \sin \phi \, d\theta \, d\phi \\ &= [\sin \theta]_0^{2\pi} \int_0^\pi \sin^2 \phi \, d\phi = 0 \end{aligned} \quad (4)$$

$$\langle n_i \rangle = 0 \quad (5)$$

$$\langle n_i n_j \rangle = \frac{1}{3} \delta_{ij} \quad (6)$$

$$\langle n_i n_k n_k \rangle = 0 \quad (7)$$

$$\langle n_i n_k n_l n_m \rangle = \frac{1}{15} (\delta_{ik} \delta_{lm} + \delta_{il} \delta_{km} + \delta_{im} \delta_{kl}) \quad (8)$$

$$\langle (\mathbf{a} \cdot \hat{\mathbf{n}})^2 \rangle = \frac{1}{3} a^2 \quad (9)$$

$$\langle (\mathbf{a} \cdot \hat{\mathbf{n}})(\mathbf{b} \cdot \hat{\mathbf{n}}) \rangle = \frac{1}{3} \mathbf{a} \cdot \mathbf{b} \quad (10)$$

$$\langle (\mathbf{a} \cdot \hat{\mathbf{n}})\hat{\mathbf{n}} \rangle = \frac{1}{3} \mathbf{a} \quad (11)$$

$$\langle (\mathbf{a} \times \hat{\mathbf{n}})^2 \rangle = \frac{2}{3} a^2 \quad (12)$$

$$\langle (\mathbf{a} \times \hat{\mathbf{n}}) \cdot (\mathbf{b} \times \hat{\mathbf{n}}) \rangle = \frac{2}{3} \mathbf{a} \cdot \mathbf{b}, \quad (13)$$

and

$$\begin{aligned} &\langle (\mathbf{a} \cdot \hat{\mathbf{n}})(\mathbf{b} \cdot \hat{\mathbf{n}})(\mathbf{c} \cdot \hat{\mathbf{n}})(\mathbf{d} \cdot \hat{\mathbf{n}}) \rangle \\ &= \frac{1}{15} [(bfa \cdot \mathbf{b})(bfc \cdot \mathbf{d}) + (bfa \cdot \mathbf{c})(bfb \cdot \mathbf{d}) + (bfa \cdot \mathbf{d})(bfb \cdot \mathbf{c})] \end{aligned} \quad (14)$$

where  $\delta_{ij}$  is the KRONECKER DELTA,  $\mathbf{a} \cdot \mathbf{b}$  is a DOT PRODUCT, and EINSTEIN SUMMATION has been used.

### Vector Bundle

A special class of FIBER BUNDLE in which the FIBER is a VECTOR SPACE. Technically, a little more is required; namely, if  $f: E \rightarrow B$  is a BUNDLE with FIBER  $\mathbb{R}^n$ , to be a vector bundle, all of the FIBERS  $f^{-1}(x)$  for

$x \in B$  need to have a coherent VECTOR SPACE structure. One way to say this is that the "trivializations"  $h : f^{-1}(U) \rightarrow U \times \mathbb{R}^n$ , are FIBER-for-FIBER VECTOR SPACE ISOMORPHISMS.

see also BUNDLE, FIBER, FIBER BUNDLE, LIE ALGEBROID, STABLE EQUIVALENCE, TANGENT MAP, VECTOR SPACE, WHITNEY SUM

### Vector Derivative

The basic types of derivatives operating on a VECTOR FIELD are the CURL  $\nabla \times$ , DIVERGENCE  $\nabla \cdot$ , and GRADIENT  $\nabla$ .

Vector derivative identities involving the CURL include

$$\nabla \times (k\mathbf{A}) = k\nabla \times \mathbf{A} \quad (1)$$

$$\nabla \times (f\mathbf{A}) = f(\nabla \times \mathbf{A}) + (\nabla f) \times \mathbf{A} \quad (2)$$

$$\nabla \times (\mathbf{A} \times \mathbf{B}) = (\mathbf{B} \cdot \nabla)\mathbf{A} - (\mathbf{A} \cdot \nabla)\mathbf{B} + \mathbf{A}(\nabla \cdot \mathbf{B}) - \mathbf{B}(\nabla \cdot \mathbf{A}) \quad (3)$$

$$\nabla \times \left( \frac{\mathbf{A}}{f} \right) = \frac{f(\nabla \times \mathbf{A}) + \mathbf{A} \times (\nabla f)}{f^2} \quad (4)$$

$$\nabla \times (\mathbf{A} + \mathbf{B}) = \nabla \times \mathbf{A} + \nabla \times \mathbf{B}. \quad (5)$$

In SPHERICAL COORDINATES,

$$\nabla \times \mathbf{r} = \mathbf{0} \quad (6)$$

$$\nabla \times \hat{\mathbf{r}} = \mathbf{0} \quad (7)$$

$$\begin{aligned} \nabla \times [rf(r)] &= f(r)(\nabla \times \mathbf{r}) + [\nabla f(r)] \times \mathbf{r} \\ &= f(r)(\mathbf{0}) + \frac{df}{dr} \hat{\mathbf{r}} \times \mathbf{r} = \mathbf{0} + \mathbf{0} = \mathbf{0}. \end{aligned} \quad (8)$$

Vector derivative identities involving the DIVERGENCE include

$$\nabla \cdot (k\mathbf{A}) = k\nabla \cdot \mathbf{A} \quad (9)$$

$$\nabla \cdot (f\mathbf{A}) = f(\nabla \cdot \mathbf{A}) + (\nabla f) \cdot \mathbf{A} \quad (10)$$

$$\nabla \cdot (\mathbf{A} \times \mathbf{B}) = \mathbf{B} \cdot (\nabla \times \mathbf{A}) - \mathbf{A} \cdot (\nabla \times \mathbf{B}) \quad (11)$$

$$\nabla \cdot \left( \frac{\mathbf{A}}{f} \right) = \frac{f(\nabla \cdot \mathbf{A}) - (\nabla f) \cdot \mathbf{A}}{f^2} \quad (12)$$

$$\nabla \cdot (\mathbf{A} + \mathbf{B}) = \nabla \cdot \mathbf{A} + \nabla \cdot \mathbf{B} \quad (13)$$

$$\nabla(\mathbf{u}\mathbf{v}) = \mathbf{u}\nabla \cdot \mathbf{v} + (\nabla \mathbf{u}) \cdot \mathbf{v}. \quad (14)$$

In SPHERICAL COORDINATES,

$$\nabla \cdot \mathbf{r} = 3 \quad (15)$$

$$\nabla \cdot \hat{\mathbf{r}} = \frac{2}{r} \quad (16)$$

$$\nabla \cdot [rf(r)] = \frac{\partial}{\partial x}[xf(r)] + \frac{\partial}{\partial y}[yf(r)] + \frac{\partial}{\partial z}[zf(r)] \quad (17)$$

$$\frac{\partial}{\partial x}[xf(r)] = x \frac{\partial f}{\partial x} + f = x \frac{\partial f}{\partial r} \frac{\partial r}{\partial x} + f \quad (18)$$

$$\frac{\partial r}{\partial x} = \frac{\partial}{\partial x}(x^2 + y^2 + z^2)^{1/2} = x(x^2 + y^2 + z^2)^{-1/2} = \frac{x}{r} \quad (19)$$

$$\frac{\partial}{\partial x}[xf(r)] = \frac{x^2}{r} \frac{df}{dr} + f. \quad (20)$$

By symmetry,

$$\nabla \cdot [rf(r)] = 3f(r) + \frac{1}{r}(x^2 + y^2 + z^2) \frac{df}{dr} = 3f(r) + r \frac{df}{dr} \quad (21)$$

$$\nabla \cdot (\hat{\mathbf{r}}f(r)) = \frac{3}{r}f(r) + \frac{df}{dr} \quad (22)$$

$$\nabla \cdot (\hat{\mathbf{r}}r^n) = 3r^{n-1} + (n-1)r^{n-1} = (n+2)r^{n-1}. \quad (23)$$

Vector derivative identities involving the GRADIENT include

$$\nabla(kf) = k\nabla f \quad (24)$$

$$\nabla(fg) = f\nabla g + g\nabla f \quad (25)$$

$$\begin{aligned} \nabla(\mathbf{A} \cdot \mathbf{B}) &= \mathbf{A} \times (\nabla \times \mathbf{B}) + \mathbf{B} \times (\nabla \times \mathbf{A}) \\ &\quad + (\mathbf{A} \cdot \nabla)\mathbf{B} + (\mathbf{B} \cdot \nabla)\mathbf{A} \end{aligned} \quad (26)$$

$$\begin{aligned} \nabla(\mathbf{A} \cdot \nabla f) &= \mathbf{A} \times (\nabla \times \nabla f) + \nabla f \times (\nabla \times \mathbf{A}) \\ &\quad + \mathbf{A} \cdot \nabla(\nabla f) + \nabla f \cdot \nabla \mathbf{A} \end{aligned} \quad (27)$$

$$\nabla \left( \frac{f}{g} \right) = \frac{g\nabla f - f\nabla g}{g^2} \quad (28)$$

$$\nabla(f+g) = \nabla f + \nabla g \quad (29)$$

$$\nabla(\mathbf{A} \cdot \mathbf{A}) = 2\mathbf{A} \times (\nabla \times \mathbf{A}) + 2(\mathbf{A} \cdot \nabla)\mathbf{A} \quad (30)$$

$$(\mathbf{A} \cdot \nabla)\mathbf{A} = \nabla(\frac{1}{2}\mathbf{A}^2) - \mathbf{A} \times (\nabla \times \mathbf{A}). \quad (31)$$

Vector second derivative identities include

$$\nabla^2 t \equiv \nabla \cdot (\nabla t) = \frac{\partial^2 t}{\partial x^2} + \frac{\partial^2 t}{\partial y^2} + \frac{\partial^2 t}{\partial z^2} \quad (32)$$

$$\nabla^2 \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \nabla \times (\nabla \times \mathbf{A}). \quad (33)$$

This very important second derivative is known as the LAPLACIAN.

$$\nabla \times (\nabla t) = \mathbf{0} \quad (34)$$

$$\nabla(\nabla \cdot \mathbf{A}) = \nabla^2 \mathbf{A} + \nabla \times (\nabla \times \mathbf{A}) \quad (35)$$

$$\nabla \cdot (\nabla \times \mathbf{A}) = 0 \quad (36)$$

$$\nabla \times (\nabla \times \mathbf{A}) = \nabla(\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A}$$

$$\begin{aligned} \nabla \times (\nabla^2 \mathbf{A}) &= \nabla \times [\nabla(\nabla \cdot \mathbf{A})] - \nabla \times [\nabla \times (\nabla \times \mathbf{A})] \\ &= -\nabla \times [\nabla \times (\nabla \times \mathbf{A})] \\ &= -\{\nabla[\nabla \cdot (\nabla \times \mathbf{A})] - \nabla^2(\nabla \times \mathbf{A})\} \\ &= \nabla^2(\nabla \times \mathbf{A}) \end{aligned} \quad (37)$$

$$\begin{aligned} \nabla^2(\nabla \cdot \mathbf{A}) &= \nabla \cdot [\nabla(\nabla \cdot \mathbf{A})] \\ &= \nabla \cdot [\nabla^2 \mathbf{A} + \nabla \times (\nabla \times \mathbf{A})] = \nabla \cdot (\nabla^2 \mathbf{A}) \end{aligned} \quad (38)$$

$$\begin{aligned} \nabla^2[\nabla \times (\nabla \times \mathbf{A})] &= \nabla^2[\nabla(\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A}] \\ &= \nabla^2[\nabla(\nabla \cdot \mathbf{A})] - \nabla^4 \mathbf{A} \end{aligned} \quad (39)$$

$$\nabla \times [\nabla^2(\nabla \times \mathbf{A})] = \nabla^2[\nabla(\nabla \cdot \mathbf{A})] - \nabla^4 \mathbf{A} \quad (40)$$

$$\begin{aligned} \nabla^4 \mathbf{A} &= -\nabla^2[\nabla \times (\nabla \times \mathbf{A})] + \nabla^2[\nabla(\nabla \cdot \mathbf{A})] \\ &= \nabla \times [\nabla^2(\nabla \times \mathbf{A})] - \nabla^2[\nabla \times (\nabla \times \mathbf{A})]. \end{aligned} \quad (41)$$

Combination identities include

$$\mathbf{A} \times (\nabla \mathbf{A}) = \frac{1}{2} \nabla (\mathbf{A} \cdot \mathbf{A}) - (\mathbf{A} \cdot \nabla) \mathbf{A} \quad (42)$$

$$\nabla \times (\phi \nabla \phi) = \phi \nabla \times (\nabla \phi) + (\nabla \phi) \times (\nabla \phi) = \mathbf{0} \quad (43)$$

$$(\mathbf{A} \cdot \nabla) \hat{\mathbf{r}} = \frac{\mathbf{A} - \hat{\mathbf{r}}(\mathbf{A} \cdot \hat{\mathbf{r}})}{r} \quad (44)$$

$$\nabla f \cdot \mathbf{A} = \nabla \cdot (f \mathbf{A}) - f(\nabla \cdot \mathbf{A}) \quad (45)$$

$$f(\nabla \cdot \mathbf{A}) = \nabla \cdot (f \mathbf{A}) - \mathbf{A} \nabla f, \quad (46)$$

where (45) and (46) follow from divergence rule (2).

### Vector Direct Product

Given VECTORS  $\mathbf{u}$  and  $\mathbf{v}$ , the vector direct product is

$$\mathbf{uv} \equiv \mathbf{u} \otimes \mathbf{v}^T,$$

where  $\otimes$  is the MATRIX DIRECT PRODUCT and  $\mathbf{v}^T$  is the matrix TRANSPOSE. For  $3 \times 3$  vectors

$$\mathbf{uv} = \begin{bmatrix} u_1 \mathbf{v}^T \\ u_2 \mathbf{v}^T \\ u_3 \mathbf{v}^T \end{bmatrix} = \begin{bmatrix} u_1 v_1 & u_1 v_2 & u_1 v_3 \\ u_2 v_1 & u_2 v_2 & u_2 v_3 \\ u_3 v_1 & u_3 v_2 & u_3 v_3 \end{bmatrix}.$$

Note that if  $\mathbf{u} = \hat{\mathbf{x}}_i$ , then  $u_j = \delta_{ij}$ , where  $\delta_{ij}$  is the KRONECKER DELTA.

see also MATRIX DIRECT PRODUCT, SHERMAN-MORRISON FORMULA, WOODBURY FORMULA

### Vector Division

There is no unique solution  $\mathbf{A}$  to the MATRIX equation  $\mathbf{y} = \mathbf{A}\mathbf{x}$  unless  $\mathbf{x}$  is PARALLEL to  $\mathbf{y}$ , in which case  $\mathbf{A}$  is a SCALAR. Therefore, vector division is not defined.

see also MATRIX, SCALAR

### Vector Field

A MAP  $\mathbf{f} : \mathbb{R}^n \mapsto \mathbb{R}^n$  which assigns each  $\mathbf{x}$  a VECTOR FUNCTION  $\mathbf{f}(\mathbf{x})$ . FLOWS are generated by vector fields and vice versa. A vector field is a SECTION of its TANGENT BUNDLE.

see also FLOW, SCALAR FIELD, SEIFERT CONJECTURE, TANGENT BUNDLE, VECTOR, WILSON PLUG

- Morse, P. M. and Feshbach, H. "Vector Fields." §1.2 in *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 8–21, 1953.

### Vector Function

A function of one or more variables whose RANGE is 3-dimensional, as compared to a SCALAR FUNCTION, whose RANGE is 1-dimensional.

see also COMPLEX FUNCTION, REAL FUNCTION, SCALAR FUNCTION

### Vector Harmonic

see VECTOR SPHERICAL HARMONIC

### Vector Integral

The following vector integrals are related to the CURL THEOREM. If

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}(x, y, z), \quad (1)$$

then

$$\int_C ds \times \mathbf{P} = \int_S (d\mathbf{a} \times \nabla) \times \mathbf{P}. \quad (2)$$

If

$$\mathbf{F} \equiv \mathbf{c} F, \quad (3)$$

then

$$\int_C F ds = \int_S d\mathbf{a} \times \nabla F. \quad (4)$$

The following are related to the DIVERGENCE THEOREM. If

$$\mathbf{F} \equiv \mathbf{c} \times \mathbf{P}(x, y, z), \quad (5)$$

then

$$\int_V \nabla \times \mathbf{F} dV = \int_S d\mathbf{a} \times \mathbf{F}. \quad (6)$$

Finally, if

$$\mathbf{F} \equiv \mathbf{c} F, \quad (7)$$

then

$$\int_V \nabla F dV = \int_S F d\mathbf{a}. \quad (8)$$

see also CURL THEOREM, DIVERGENCE THEOREM, GRADIENT THEOREM, GREEN'S FIRST IDENTITY, GREEN'S SECOND IDENTITY, LINE INTEGRAL, SURFACE INTEGRAL, VECTOR DERIVATIVE, VOLUME INTEGRAL

### Vector Norm

Given an  $n$ -D VECTOR

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix},$$

a vector norm  $\|\mathbf{x}\|$  (sometimes written simply  $|\mathbf{x}|$ ) is a NONNEGATIVE number satisfying

1.  $\|\mathbf{x}\| > 0$  when  $\mathbf{x} \neq \mathbf{0}$  and  $\|\mathbf{x}\| = 0$  IFF  $\mathbf{x} = \mathbf{0}$ ,
2.  $\|k\mathbf{x}\| = |k| \|\mathbf{x}\|$  for any SCALAR  $k$ ,
3.  $\|\mathbf{x} + \mathbf{y}\| \leq \|\mathbf{x}\| + \|\mathbf{y}\|$ .

see also COMPATIBLE, MATRIX NORM, NATURAL NORM, NORM

#### References

Gradshteyn, I. S. and Ryzhik, I. M. *Tables of Integrals, Series, and Products*, 5th ed. San Diego, CA: Academic Press, p. 1114, 1980.

### Vector Ordering

If the first NONZERO component of the vector difference  $\mathbf{A} - \mathbf{B}$  is  $> 0$ , then  $\mathbf{A} \succ \mathbf{B}$ . If the first NONZERO component of  $\mathbf{A} - \mathbf{B}$  is  $< 0$ , then  $\mathbf{A} \prec \mathbf{B}$ .

see also PRECEDES, SUCCEEDS

### Vector Potential

A function  $\mathbf{A}$  such that

$$\mathbf{B} \equiv \nabla \times \mathbf{A}.$$

The most common use of a vector potential is the representation of a magnetic field. If a VECTOR FIELD has zero DIVERGENCE, it may be represented by a vector potential.

see also DIVERGENCE, HELMHOLTZ'S THEOREM, POTENTIAL FUNCTION, SOLENOIDAL FIELD, VECTOR FIELD

### Vector Quadruple Product

$$(\mathbf{A} \times \mathbf{B}) \cdot (\mathbf{C} \times \mathbf{D}) = (\mathbf{A} \cdot \mathbf{C})(\mathbf{B} \cdot \mathbf{D}) - (\mathbf{A} \cdot \mathbf{D})(\mathbf{B} \cdot \mathbf{C}) \quad (1)$$

$$\begin{aligned} (\mathbf{A} \times \mathbf{B})^2 &\equiv (\mathbf{A} \times \mathbf{B}) \cdot (\mathbf{A} \times \mathbf{B}) \\ &= (\mathbf{A} \cdot \mathbf{A})(\mathbf{B} \cdot \mathbf{B}) - (\mathbf{A} \cdot \mathbf{B})(\mathbf{B} \cdot \mathbf{A}) \\ &= \mathbf{A}^2 \mathbf{B}^2 - (\mathbf{A} \cdot \mathbf{B})^2 \end{aligned} \quad (2)$$

$$\mathbf{A} \times (\mathbf{B} \times (\mathbf{C} \times \mathbf{D})) = \mathbf{B}(\mathbf{A} \cdot (\mathbf{C} \times \mathbf{D})) - (\mathbf{A} \cdot \mathbf{B})(\mathbf{C} \times \mathbf{D}) \quad (3)$$

$$\begin{aligned} (\mathbf{A} \times \mathbf{B}) \times (\mathbf{C} \times \mathbf{D}) &= [\mathbf{A}, \mathbf{B}, \mathbf{D}]\mathbf{C} - [\mathbf{A}, \mathbf{B}, \mathbf{C}]\mathbf{D} \\ &= (\mathbf{C} \times \mathbf{D}) \times (\mathbf{B} \times \mathbf{A}) = [\mathbf{C}, \mathbf{D}, \mathbf{A}]\mathbf{D} - [\mathbf{C}, \mathbf{D}, \mathbf{B}]\mathbf{A}, \end{aligned} \quad (4)$$

where  $[\mathbf{A}, \mathbf{B}, \mathbf{D}]$  denotes the VECTOR TRIPLE PRODUCT. Equation (1) is known as LAGRANGE'S IDENTITY. see also LAGRANGE'S IDENTITY, VECTOR TRIPLE PRODUCT

### Vector Space

A vector space over  $\mathbb{R}^n$  is a set of VECTORS for which any VECTORS  $\mathbf{X}$ ,  $\mathbf{Y}$ , and  $\mathbf{Z} \in \mathbb{R}^n$  and any SCALARS  $r, s \in \mathbb{R}$  have the following properties:

1. COMMUTATIVITY:

$$\mathbf{X} + \mathbf{Y} = \mathbf{Y} + \mathbf{X}.$$

2. ASSOCIATIVITY of vector addition:

$$(\mathbf{X} + \mathbf{Y}) + \mathbf{Z} = \mathbf{X} + (\mathbf{Y} + \mathbf{Z}).$$

3. Additive identity: For all  $\mathbf{X}$ ,

$$\mathbf{0} + \mathbf{X} = \mathbf{X} + \mathbf{0} = \mathbf{X}.$$

4. Existence of additive inverse: For any  $\mathbf{X}$ , there exists a  $-\mathbf{X}$  such that

$$\mathbf{X} + (-\mathbf{X}) = \mathbf{0}.$$

5. ASSOCIATIVITY of scalar multiplication:

$$r(s\mathbf{X}) = (rs)\mathbf{X}.$$

6. DISTRIBUTIVITY of scalar sums:

$$(r + s)\mathbf{X} = r\mathbf{X} + s\mathbf{X}.$$

7. DISTRIBUTIVITY of vector sums:

$$r(\mathbf{X} + \mathbf{Y}) = r\mathbf{X} + r\mathbf{Y}.$$

8. Scalar multiplication identity:

$$1\mathbf{X} = \mathbf{X}.$$

An  $n$ -D vector space of characteristic two has

$$S(k, n) = (2^n - 2^0)(2^n - 2^1) \cdots (2^n - 2^{k-1})$$

distinct SUBSPACES of DIMENSION  $k$ .

A MODULE is abstractly similar to a vector space, but it uses a RING to define COEFFICIENTS instead of the FIELD used for vector spaces. MODULES have COEFFICIENTS in much more general algebraic objects.

see also BANACH SPACE, FIELD, FUNCTION SPACE, HILBERT SPACE, INNER PRODUCT SPACE, MODULE, RING, TOPOLOGICAL VECTOR SPACE

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 530-534, 1985.

### Vector Spherical Harmonic

The SPHERICAL HARMONICS can be generalized to vector spherical harmonics by looking for a SCALAR FUNCTION  $\psi$  and a constant VECTOR  $\mathbf{c}$  such that

$$\begin{aligned} \mathbf{M} &\equiv \nabla \times (\mathbf{c}\psi) = \psi(\nabla \times \mathbf{c}) + (\nabla\psi) \times \mathbf{c} \\ &= (\nabla\psi) \times \mathbf{c} = -\mathbf{c} \times \nabla\psi \end{aligned} \quad (1)$$

so

$$\nabla \cdot \mathbf{M} = 0. \quad (2)$$

Now use the vector identities

$$\begin{aligned} \nabla^2 \mathbf{M} &= \nabla^2 (\nabla \times \mathbf{M}) = \nabla \times (\nabla^2 \mathbf{M}) \\ &= \nabla \times (\nabla^2 \mathbf{c}\psi) = \nabla \times (\mathbf{c}\nabla^2 \psi) \end{aligned} \quad (3)$$

$$k^2 \mathbf{M} = k^2 \nabla \times (\mathbf{c}\psi) = \nabla \times (\mathbf{c}\nabla^2 \psi), \quad (4)$$

so

$$\nabla^2 \mathbf{M} + k^2 \mathbf{M} = \nabla \times [\mathbf{c}(\nabla^2 \psi + k^2 \psi)], \quad (5)$$

and  $\mathbf{M}$  satisfies the vector HELMHOLTZ DIFFERENTIAL EQUATION if  $\psi$  satisfies the scalar HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2 \psi + k^2 \psi = 0. \quad (6)$$

Construct another vector function

$$\mathbf{N} \equiv \frac{\nabla \times \mathbf{M}}{k}, \quad (7)$$

which also satisfies the vector HELMHOLTZ DIFFERENTIAL EQUATION since

$$\begin{aligned} \nabla^2 \mathbf{N} &= \frac{1}{k} \nabla^2 (\nabla \times \mathbf{M}) = \frac{1}{k} \nabla \times (\nabla^2 \mathbf{M}) \\ &= \frac{1}{k} \nabla \times (-k^2 \mathbf{M}) = -k \nabla \times \mathbf{M} = -k^2 \mathbf{N}, \end{aligned} \quad (8)$$

which gives

$$\nabla^2 \mathbf{N} + k^2 \mathbf{N} = 0. \quad (9)$$

We have the additional identity

$$\begin{aligned} \nabla \times \mathbf{N} &= \frac{1}{k} \nabla \times (\nabla \times \mathbf{M}) = \frac{1}{k} \nabla (\nabla \cdot \mathbf{M}) \\ &= \frac{1}{k} \nabla^2 \mathbf{M} - \frac{1}{k} \nabla^2 \mathbf{M} = \frac{-\nabla^2 \mathbf{M}}{k} = k \mathbf{M}. \end{aligned} \quad (10)$$

In this formalism,  $\psi$  is called the generating function and  $\mathbf{c}$  is called the PILOT VECTOR. The choice of generating function is determined by the symmetry of the scalar equation, i.e., it is chosen to solve the desired scalar differential equation. If  $\mathbf{M}$  is taken as

$$\mathbf{M} = \nabla \times (\mathbf{r}\psi), \quad (11)$$

where  $\mathbf{r}$  is the radius vector, then  $\mathbf{M}$  is a solution to the vector wave equation in spherical coordinates. If we want vector solutions which are tangential to the radius vector,

$$\mathbf{M} \cdot \mathbf{r} = \mathbf{r} \cdot (\nabla \psi \times \mathbf{c}) = (\nabla \psi)(\mathbf{c} \times \mathbf{r}) = 0, \quad (12)$$

so

$$\mathbf{c} \times \mathbf{r} = \mathbf{0} \quad (13)$$

and we may take

$$\mathbf{c} = \mathbf{r} \quad (14)$$

(Arfken 1985, pp. 707–711; Bohren and Huffman 1983, p. 88).

A number of conventions are in use. Hill (1954) defines

$$\begin{aligned} \mathbf{V}_l^m &= -\sqrt{\frac{l+1}{2l+1}} Y_l^m \hat{\mathbf{r}} + \frac{1}{\sqrt{(l+1)(2l+1)}} \frac{\partial Y_l^m}{\partial \theta} \hat{\boldsymbol{\theta}} \\ &\quad + iM \sqrt{(l+1)(2l+1)} \sin \theta Y_l^m \hat{\boldsymbol{\phi}} \end{aligned} \quad (15)$$

$$\begin{aligned} \mathbf{W}_l^m &= \sqrt{\frac{l}{2l+1}} Y_l^m \hat{\mathbf{r}} + \frac{1}{\sqrt{l(2l+1)}} \frac{\partial Y_l^m}{\partial \theta} \hat{\boldsymbol{\theta}} \\ &\quad + \frac{iM}{\sqrt{l(2l+1)} \sin \theta} Y_l^m \hat{\boldsymbol{\phi}} \end{aligned} \quad (16)$$

$$\mathbf{X}_l^m = -\frac{M}{\sqrt{l(l+1)} \sin \theta} Y_l^m \hat{\boldsymbol{\theta}} - \frac{i}{\sqrt{l(l+1)}} \frac{\partial Y_l^m}{\partial \theta} \hat{\boldsymbol{\phi}}. \quad (17)$$

Morse and Feshbach (1953) define vector harmonics called  $\mathbf{B}$ ,  $\mathbf{C}$ , and  $\mathbf{P}$  using rather complicated expressions.

#### Vector Transformation Law

The set of  $n$  quantities  $v_j$  are components of an  $n$ -D VECTOR  $\mathbf{v}$  IFF, under ROTATION,

$$v'_i = a_{ij} v_j$$

for  $i = 1, 2, \dots, n$ . The DIRECTION COSINES between  $x'_i$  and  $x_j$  are

$$a_{ij} \equiv \frac{\partial x'_i}{\partial x_j} = \frac{\partial x_j}{\partial x'_i}.$$

They satisfy the orthogonality condition

$$a_{ij} a_{ik} = \frac{\partial x_j}{\partial x'_i} \frac{\partial x'_i}{\partial x_k} = \frac{\partial x_j}{\partial x_k} = \delta_{jk},$$

where  $\delta_{jk}$  is the KRONECKER DELTA.

see also TENSOR, VECTOR

**Vector Triple Product**

The triple product can be written in terms of the LEVI-CIVITA SYMBOL  $\epsilon_{ijk}$  as

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \epsilon_{ijk} A^i B^j C^k. \quad (1)$$

The BAC-CAB RULE can be written in the form

$$\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) - \mathbf{C}(\mathbf{A} \cdot \mathbf{B}) \quad (2)$$

$$\begin{aligned} (\mathbf{A} \times \mathbf{B}) \times \mathbf{C} &= -\mathbf{C} \times (\mathbf{A} \times \mathbf{B}) \\ &= -\mathbf{A}(\mathbf{B} \cdot \mathbf{C}) + \mathbf{B}(\mathbf{A} \cdot \mathbf{C}). \end{aligned} \quad (3)$$

Addition identities are

$$\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = \mathbf{B} \cdot (\mathbf{C} \times \mathbf{A}) = \mathbf{C} \cdot (\mathbf{A} \times \mathbf{B}) \quad (4)$$

$$[\mathbf{A}, \mathbf{B}, \mathbf{C}]\mathbf{D} = [\mathbf{D}, \mathbf{B}, \mathbf{C}]\mathbf{A} + [\mathbf{A}, \mathbf{D}, \mathbf{C}]\mathbf{B} + [\mathbf{A}, \mathbf{B}, \mathbf{D}]\mathbf{C} \quad (5)$$

$$[\mathbf{q}, \mathbf{q}', \mathbf{q}''][\mathbf{r}, \mathbf{r}', \mathbf{r}''] = \begin{vmatrix} \mathbf{q} \cdot \mathbf{r} & \mathbf{q} \cdot \mathbf{r}' & \mathbf{q} \cdot \mathbf{r}'' \\ \mathbf{q}' \cdot \mathbf{r} & \mathbf{q}' \cdot \mathbf{r}' & \mathbf{q}' \cdot \mathbf{r}'' \\ \mathbf{q}'' \cdot \mathbf{r} & \mathbf{q}'' \cdot \mathbf{r}' & \mathbf{q}'' \cdot \mathbf{r}'' \end{vmatrix}. \quad (6)$$

**References**

Arfken, G. "Triple Scalar Product, Triple Vector Product." §1.5 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 26–33, 1985.

**Vee**

The symbol  $\vee$  variously means "disjunction" (in LOGIC) or "join" (for a LATTICE).

see also WEDGE

**Velocity**

$$\mathbf{v} \equiv \frac{d\mathbf{r}}{dt},$$

where  $\mathbf{r}$  is the POSITION VECTOR and  $d/dt$  is the derivative with respect to time. Expressed in terms of the ARC LENGTH,

$$\mathbf{v} = \frac{ds}{dt} \hat{\mathbf{T}},$$

where  $\hat{\mathbf{T}}$  is the unit TANGENT VECTOR, so the SPEED (which is the magnitude of the velocity) is

$$v \equiv |\mathbf{v}| = \frac{ds}{dt} = |\mathbf{r}'(t)|.$$

see also ANGULAR VELOCITY, POSITION VECTOR, SPEED

**Venn Diagram**

The simplest Venn diagram consists of three symmetrically placed mutually intersecting CIRCLES. It is used in LOGIC theory to represent collections of sets. The region of intersection of the three CIRCLES  $A \cap B \cap C$ , in the special case of the center of each being located at the intersection of the other two, is called a REULEAUX TRIANGLE.

In general, an order  $n$  Venn diagram is a collection of  $n$  simple closed curves in the PLANE such that

1. The curves partition the PLANE into  $2^n$  connected regions, and
2. Each SUBSET  $S$  of  $\{1, 2, \dots, n\}$  corresponds to a unique region formed by the intersection of the interiors of the curves in  $S$  (Ruskey).

**Verging Construction**

see NEUSIS CONSTRUCTION

**Verhulst Model**

see LOGISTIC MAP

**Veronese Surface**

A smooth 2-D surface given by embedding the PROJECTIVE PLANE into projective 5-space by the homogeneous parametric equations

$$v(x, y, z) = (x^2, y^2, z^2, xy, xz, yz).$$

The surface can be projected smoothly into 4-space, but all 3-D projections have singularities (Coffman). The projections of these surfaces in 3-D are called STEINER SURFACES. The VOLUME of the Veronese surface is  $2\pi^2$ .

see also STEINER SURFACE

Abramowitz, M. and Stegun, C. A. (Eds.). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, p. 78, 1972.

**Vertex Angle**

The point about which an ANGLE is measured is called the angle's vertex, and the angle associated with a given vertex is called the vertex angle.

see also ANGLE

**Vertex Coloring**

BRELAZ'S HEURISTIC ALGORITHM can be used to find a good, but not necessarily minimal, VERTEX coloring of a GRAPH.

see also BRELAZ'S HEURISTIC ALGORITHM, COLORING

**Vertex Connectivity**

The minimum number of VERTICES whose deletion from a GRAPH disconnects it.

see also EDGE CONNECTIVITY

**Vertex Cover**

see HITTING SET

**Vertex Degree**

The degree of a VERTEX of a GRAPH is the number of EDGES which touch the VERTEX, also called the LOCAL DEGREE. The VERTEX degree of a point  $A$  in a GRAPH, denoted  $\rho(A)$ , satisfies

$$\sum_{i=1}^n \rho(A_i) = 2E,$$

where  $E$  is the total number of EDGES. DIRECTED GRAPHS have two types of degrees, known as the IN-DEGREE and the OUTDEGREE.

see also DIRECTED GRAPH, INDEGREE, LOCAL DEGREE, OUTDEGREE

**Vertex Enumeration**

A CONVEX POLYHEDRON is defined as the set of solutions to a system of linear inequalities

$$\mathbf{m}\mathbf{x} \leq \mathbf{b},$$

where  $\mathbf{m}$  is a REAL  $s \times d$  MATRIX and  $\mathbf{b}$  is a REAL  $s$ -VECTOR. Given  $\mathbf{m}$  and  $\mathbf{b}$ , vertex enumeration is the determination of the polyhedron's VERTICES.

see also CONVEX POLYHEDRON, POLYHEDRON

**Vertex Figure**

The line joining the MIDPOINTS of adjacent sides in a POLYGON is called the polygon's vertex figure. For a regular  $n$ -gon with side length  $s$ ,

$$v = s \cos\left(\frac{\pi}{n}\right).$$

For a POLYHEDRON, the faces that join at a VERTEX form a solid angle whose section by the plane is the vertex figure.

see also TRUNCATION

**Vertex (Graph)**

A point of a GRAPH, also called a NODE.

see also EDGE (GRAPH), NULL GRAPH, TAIT COLORING, TAIT CYCLE, TAIT'S HAMILTONIAN GRAPH CONJECTURE, VERTEX (POLYGON)

**Vertex (Parabola)**

For a PARABOLA oriented vertically and opening upwards, the vertex is the point where the curve reaches a minimum.

## Vertex (Polygon)

A point at which two EDGES of a POLYGON meet.

see also PRINCIPAL VERTEX, VERTEX (GRAPH), VERTEX (POLYHEDRON)

## Vertex (Polyhedron)

A point at which three or more EDGES of a POLYHEDRON meet. The concept can also be generalized to a POLYTOPE.

see also VERTEX (GRAPH), VERTEX (POLYGON)

## Vertex (Polytope)

The vertex of a POLYTOPE is a point where edges of the POLYTOPE meet.

## Vertical

Oriented in an up-down position.

see also HORIZONTAL

## Vertical-Horizontal Illusion

The HORIZONTAL line segment in the above figure appears to be shorter than the VERTICAL line segment, despite the fact that it has the same length.

see also ILLUSION, MÜLLER-LYER ILLUSION, POGGENDORFF ILLUSION, PONZO'S ILLUSION

## References

## Vibration Problem

Solution of a system of second-order homogeneous ordinary differential equations with constant COEFFICIENTS of the form

$$\frac{d^2 \mathbf{x}}{dt^2} + \mathbf{B} \mathbf{x} = 0,$$

where  $\mathbf{B}$  is a POSITIVE DEFINITE MATRIX. To solve the vibration problem,

1. Solve the CHARACTERISTIC EQUATION of  $\mathbf{B}$  to get EIGENVALUES  $\lambda_1, \dots, \lambda_n$ . Define  $\omega_i \equiv \sqrt{\lambda_i}$ .
2. Compute the corresponding EIGENVECTORS  $\mathbf{e}_1, \dots, \mathbf{e}_n$ .
3. The normal modes of oscillation are given by  $\mathbf{x}_1 = A_1 \sin(\omega_1 t + \alpha_1) \mathbf{e}_1, \dots, \mathbf{x}_n = A_n \sin(\omega_n t + \alpha_n) \mathbf{e}_n$ , where  $A_1, \dots, A_n$  and  $\alpha_1, \dots, \alpha_n$  are arbitrary constants.
4. The general solution is  $\mathbf{x} = \sum_{i=1}^n \mathbf{x}_i$ .

**Vickery Auction**

An AUCTION in which the highest bidder wins but pays only the second-highest bid. This variation over the normal bidding procedure is supposed to encourage bidders to bid the largest amount they are willing to pay.

see also AUCTION

**Viergruppe**

The mathematical group  $Z_4 \otimes Z_4$ , also denoted  $D_2$ . Its multiplication table is

$V$	$I$	$V_1$	$V_2$	$V_3$
$I$	$V_1$	$V_2$	$V_3$	$V_4$
$V_1$	$V_1$	$I$	$V_3$	$V_2$
$V_2$	$V_2$	$V_3$	$I$	$V_1$
$V_3$	$V_3$	$V_2$	$V_1$	$I$

see also DIHEDRAL GROUP, FINITE GROUP— $Z_4$

**Vieta's Substitution**

The substitution of

$$x = w - \frac{p}{3w}$$

into the standard form CUBIC EQUATION

$$x^3 + px = q,$$

which reduces the cubic to a QUADRATIC EQUATION in  $w^3$ ,

$$(w^3)^2 - \frac{1}{27}p^3(w^3) - q = 0.$$

see also CUBIC EQUATION

**Vigesimal**

The base-20 notational system for representing REAL NUMBERS. The digits used to represent numbers using vigesimal NOTATION are 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F, G, H, I, and J. A base-20 number system was used by the Aztecs and Mayans. The Mayans compiled extensive observations of planetary positions in base-20 notation.

**Vinculum**

A horizontal line placed above multiple quantities to indicate that they form a unit. It is most commonly used to denote ROOTS ( $\sqrt{12345}$ ) and repeating decimals (0.111).

**Vinogradov's Theorem**

Every sufficiently large ODD number is a sum of three PRIMES. Proved in 1937.

see also GOLDBACH CONJECTURE

**Virtual Group**

see GROUPOID

**Visibility**

see VISIBLE POINT

**Visible Point**

Two LATTICE POINTS  $(x, y)$  and  $(x', y')$  are mutually visible if the line segment joining them contains no further LATTICE POINTS. This corresponds to the requirement that  $(x' - x, y' - y) = 1$ , where  $(m, n)$  denotes the GREATEST COMMON DIVISOR. The plots above show the first few points visible from the ORIGIN.

If a LATTICE POINT is selected at random in 2-D, the probability that it is visible from the origin is  $6/\pi^2$ . This is also the probability that two INTEGERS picked at random are RELATIVELY PRIME. If a LATTICE POINT is picked at random in  $n$ -D, the probability that it is visible

from the ORIGIN is  $1/\zeta(n)$ , where  $\zeta(n)$  is the RIEMANN ZETA FUNCTION.

An invisible figure is a POLYGON all of whose corners are invisible. There are invisible sets of every finite shape. The lower left-hand corner of the invisible squares with smallest  $x$  coordinate of AREAS 2 and 3 are (14, 20) and (104, 6200).

see also LATTICE POINT, ORCHARD VISIBILITY PROBLEM, RIEMANN ZETA FUNCTION

#### Visible Point Vector Identity

A set of identities involving  $n$ -D visible lattice points was discovered by Campbell (1994). Examples include

$$\prod_{\substack{(a,b)=1 \\ a \geq 0, b \leq 1}} (1 - y^a z^b)^{-1/b} = (1 - z)^{-1/(1-y)}$$

for  $|yz|, |z| < 1$  and

$$\prod_{\substack{(a,b,c)=1 \\ a, b \geq 0, c \leq 1}} (1 - x^a y^b z^c)^{-1/c} = (1 - z)^{-1/[(1-x)(1-y)]}$$

for  $|xyz|, |xz|, |yz|, |z| < 1$ .

#### Vitali's Convergence Theorem

Let  $f_n(z)$  be a sequence of functions, each regular in a region  $D$ , let  $|f_n(z)| \leq M$  for every  $n$  and  $z$  in  $D$ , and let  $f_n(z)$  tend to a limit as  $n \rightarrow \infty$  at a set of points having a LIMIT POINT inside  $D$ . Then  $f_n(z)$  tends uniformly to a limit in any region bounded by a contour interior to  $D$ , the limit therefore being an analytic function of  $z$ .

#### Viviani's Curve

The SPACE CURVE giving the intersection of the CYLINDER

$$(x - a)^2 + y^2 = a^2 \quad (1)$$

and the SPHERE

$$x^2 + y^2 + z^2 = 4^2. \quad (2)$$

It is given by the parametric equations

$$x = a(1 + \cos t) \quad (3)$$

$$y = a \sin t \quad (4)$$

$$z = 2a \sin(\frac{1}{2}t). \quad (5)$$

The CURVATURE and TORSION are given by

$$\kappa(t) = \frac{\sqrt{13 + 3 \cos t}}{a(3 + \cos t)^{3/2}} \quad (6)$$

$$\tau(t) = \frac{6 \cos(\frac{1}{2}t)}{a(13 + 3 \cos t)}. \quad (7)$$

#### Viviani's Theorem

For a point  $P$  inside an EQUILATERAL TRIANGLE  $\triangle ABC$ , the sum of the perpendiculars  $p_i$  from  $P$  to the sides of the TRIANGLE is equal to the ALTITUDE  $h$ . This result is simply proved as follows,

$$\triangle ABC = \triangle PBC + \triangle PCA + \triangle PAB. \quad (1)$$

With  $s$  the side length,

$$\frac{1}{2}sh = \frac{1}{2}sp_a + \frac{1}{2}sp_b + \frac{1}{2}sp_c, \quad (2)$$

so

$$h = p_a + p_b + p_c. \quad (3)$$

see also ALTITUDE, EQUILATERAL TRIANGLE

**Vojta's Conjecture**

A conjecture which treats the heights of points relative to a canonical class of a curve defined over the INTEGERS.

**Volume**

The volume of a solid body is the amount of "space" it occupies. Volume has units of LENGTH cubed (i.e., cm<sup>3</sup>, m<sup>3</sup>, in<sup>3</sup>, etc.) For example, the volume of a box (RECTANGULAR PARALLELEPIPED) of LENGTH  $L$ , WIDTH  $W$ , and HEIGHT  $H$  is given by

$$V = L \times W \times H.$$

The volume can also be computed for irregularly-shaped and curved solids such as the CYLINDER and CUBE. The

volume of a SURFACE OF REVOLUTION is particularly simple to compute due to its symmetry.

The following table gives volumes for some common SURFACES. Here  $r$  denotes the RADIUS,  $h$  the height,  $A$  the base AREA, and  $s$  the SLANT HEIGHT (Beyer 1987).

Surface	$V$
cone	$\frac{1}{3}\pi r^2 h$
conical frustum	$\frac{1}{3}\pi h(R_1^2 + R_2^2 + R_1 R_2)$
cube	$a^3$
cylinder	$\pi r^2 h$
ellipsoid	$\frac{4}{3}\pi abc$
oblate spheroid	$\frac{4}{3}\pi a^2 b$
prolate spheroid	$\frac{4}{3}\pi ab^2$
pyramid	$\frac{1}{3}Ah$
pyramidal frustum	$\frac{1}{3}h(A_1 + A_2 + \sqrt{A_1 A_2})$
sphere	$\frac{4}{3}\pi r^3$
spherical sector	$\frac{2}{3}\pi r^2 h$
spherical segment	$\frac{1}{3}\pi h^2 r(3r - h)$
torus	$2\pi^2 R r^2$

Even simple SURFACES can display surprisingly counterintuitive properties. For instance, the SURFACE OF REVOLUTION of  $y = 1/x$  around the  $x$ -axis for  $x \geq 1$  is called GABRIEL'S HORN, and has finite volume, but infinite SURFACE AREA.

The generalization of volume to  $n$  DIMENSIONS for  $n \geq 4$  is known as CONTENT.

see also ARC LENGTH, AREA, CONTENT, HEIGHT, LENGTH (SIZE), SURFACE AREA, SURFACE OF REVOLUTION, VOLUME ELEMENT, WIDTH (SIZE)

References

Beyer, W. H. *CRC Standard Mathematical Tables*, 28th ed. Boca Raton, FL: CRC Press, pp. 127–132, 1987.

**Volume Element**

A volume element is the differential element  $dV$  whose VOLUME INTEGRAL over some range in a given coordinate system gives the VOLUME of a solid,

$$V = \iiint_G dx dy dz. \quad (1)$$

In  $\mathbb{R}^n$ , the volume of the infinitesimal  $n$ -HYPERCUBE bounded by  $dx_1, \dots, dx_n$  has volume given by the WEDGE PRODUCT

$$dV = dx_1 \wedge \dots \wedge dx_n \quad (2)$$

(Gray 1993).

The use of the antisymmetric WEDGE PRODUCT instead of the symmetric product  $dx_1 \dots dx_n$  is a technical refinement often omitted in informal usage. Dropping the

wedges, the volume element for CURVILINEAR COORDINATES in  $\mathbb{R}^3$  is given by

$$dV = |(h_1 \hat{u}_1 du_1) \cdot (h_2 \hat{u}_2 du_2) \times (h_3 \hat{u}_3 du_3)| \quad (3)$$

$$= h_1 h_2 h_3 du_1 du_2 du_3 \quad (4)$$

$$= \left| \frac{\partial \mathbf{r}}{\partial u_1} \cdot \frac{\partial \mathbf{r}}{\partial u_2} \times \frac{\partial \mathbf{r}}{\partial u_3} \right| du_1 du_2 du_3 \quad (5)$$

$$= \begin{vmatrix} \frac{\partial x}{\partial u_1} & \frac{\partial x}{\partial u_2} & \frac{\partial x}{\partial u_3} \\ \frac{\partial y}{\partial u_1} & \frac{\partial y}{\partial u_2} & \frac{\partial y}{\partial u_3} \\ \frac{\partial z}{\partial u_1} & \frac{\partial z}{\partial u_2} & \frac{\partial z}{\partial u_3} \end{vmatrix} du_1 du_2 du_3 \quad (6)$$

$$= \left| \frac{\partial(x, y, z)}{\partial(u_1, u_2, u_3)} \right| du_1 du_2 du_3, \quad (7)$$

where the latter is the JACOBIAN and the  $h_i$  are SCALE FACTORS.

### von Dyck's Theorem

Let a GROUP  $G$  have a presentation

$$G = \langle x_1, \dots, x_n | r_j(x_1, \dots, x_n), j \in J \rangle$$

so that  $G = F/R$ , where  $F$  is the FREE GROUP with basis  $\{x_1, \dots, x_n\}$  and  $R$  is the NORMAL SUBGROUP generated by the  $r_j$ . If  $H$  is a GROUP with  $H = \langle y_1, \dots, y_n \rangle$  and if  $r_j(y_1, \dots, y_n) = 1$  for all  $j$ , then there is a surjective homomorphism  $G \rightarrow H$  with  $x_i \mapsto y_i$  for all  $i$ .

### von Staudt-Clausen Theorem

$$B_{2n} = A_n - \sum_{\substack{p_k \\ p_k - 1 | 2n}} \frac{1}{p_k},$$

where  $B_{2n}$  is a BERNOULLI NUMBER,  $A_n$  is an INTEGER, and the  $p_k$ s are the PRIMES satisfying  $p_k - 1 | 2k$ . For example, for  $k = 1$ , the primes included in the sum are 2 and 3, since  $(2-1) | 2$  and  $(3-1) | 2$ . Similarly, for  $k = 6$ , the included primes are (2, 3, 5, 7, 13), since (1, 2, 3, 6, 12) divide  $12 = 2 \cdot 6$ . The first few values of  $A_n$  for  $n = 1, 2, \dots$  are 1, 1, 1, 1, 1, 1, 2, -6, 56, -528, ... (Sloane's A000164).

The theorem was rediscovered by Ramanujan (Hardy 1959, p. 11) and can be proved using  $p$ -ADIC NUMBERS.

## Wallis Cosine Formula

$$\int_0^{\pi/2} \cos^n x \, dx = \begin{cases} \frac{\pi}{2} \frac{1 \cdot 3 \cdot 5 \cdots (n-1)}{2 \cdot 4 \cdot 6 \cdots n} & \text{for } n = 2, 4, \dots \\ \frac{2 \cdot 4 \cdot 6 \cdots (n-1)}{1 \cdot 3 \cdot 5 \cdots n} & \text{for } n = 3, 5, \dots \end{cases}$$

see also WALLIS FORMULA, WALLIS SINE FORMULA

## Wallis Formula

The Wallis formula follows from the INFINITE PRODUCT representation of the SINE

$$\sin x = x \prod_{n=1}^{\infty} \left( 1 - \frac{x^2}{\pi^2 n^2} \right). \quad (1)$$

Taking  $x = \pi/2$  gives

$$1 = \frac{\pi}{2} \prod_{n=1}^{\infty} \left[ 1 - \frac{1}{(2n)^2} \right] = \frac{\pi}{2} \prod_{n=1}^{\infty} \left[ \frac{(2n)^2 - 1}{(2n)^2} \right], \quad (2)$$

so

$$\frac{\pi}{2} = \prod_{n=1}^{\infty} \left[ \frac{(2n)^2}{(2n-1)(2n+1)} \right] = \frac{2 \cdot 2}{1 \cdot 3} \frac{4 \cdot 4}{3 \cdot 5} \frac{6 \cdot 6}{5 \cdot 7} \cdots \quad (3)$$

A derivation due to Y. L. Yung uses the RIEMANN ZETA FUNCTION. Define

$$F(s) \equiv -\text{Li}_s(-1) = \sum_{n=1}^{\infty} \frac{(-1)^n}{n^s}$$

$$= (1 - 2^{1-s})\zeta(s) \quad (4)$$

$$F'(s) = \sum_{n=1}^{\infty} \frac{(-1)^n \ln n}{n^s}, \quad (5)$$

so

$$F'(0) = \sum_{n=1}^{\infty} (-1)^n \ln n = -\ln 1 + \ln 2 - \ln 3 + \dots$$

$$= \ln \left( \frac{2 \cdot 4 \cdot 6 \cdots}{1 \cdot 3 \cdot 5 \cdots} \right). \quad (6)$$

Taking the derivative of the zeta function expression gives

$$\frac{d}{ds}(1 - 2^{1-s})\zeta(s) = 2^{1-s}(\ln 2)\zeta(s) + (1 - 2^{1-s})\zeta'(s) \quad (7)$$

$$\left[ \frac{d}{ds}(1 - 2^{1-s})\zeta(s) \right]_{s=0} = -\ln 2 - \zeta'(0)$$

$$= -\ln 2 + \frac{1}{2} \ln(2\pi) = \ln \left( \frac{\sqrt{2\pi}}{2} \right) = \ln \left( \sqrt{\frac{\pi}{2}} \right). \quad (8)$$

Equating and squaring then gives the Wallis formula, which can also be expressed

$$\frac{\pi}{2} = \left[ 4^{\zeta(0)} e^{-\zeta'(0)} \right]^2. \quad (9)$$

The  $q$ -ANALOG of the Wallis formula for  $q = 2$  is

$$\prod_{k=1}^{\infty} (1 - q^{-k})^{-1} = 3.4627466194 \dots \quad (10)$$

(Finch).

#### Walsh Function

Functions consisting of a number of fixed-amplitude square pulses interposed with zeros. Following Harmuth (1969), designate those with EVEN symmetry  $\text{Cal}(k, t)$  and those with ODD symmetry  $\text{Sal}(k, t)$ . Define the SEQUENCE  $k$  as half the number of zero crossings in the time base. Walsh functions with nonidentical SEQUENCES are ORTHOGONAL, as are the functions  $\text{Cal}(k, t)$  and  $\text{Sal}(k, t)$ . The product of two Walsh functions is also a Walsh function. The Walsh functions

$$\text{Wal}(k, t) = \begin{cases} \text{Cal}(k/2, t) & \text{for } k = 0, 2, 4, \dots \\ \text{Sal}((k+1)/2, t) & \text{for } k = 1, 3, 5, \dots \end{cases}$$

The Walsh functions  $\text{Cal}(k, t)$  for  $k = 0, 1, \dots, n/2 - 1$  and  $\text{Sal}(k, t)$  for  $k = 1, 2, \dots, n/2$  are given by the rows of the HADAMARD MATRIX  $H_n$ .

**Ward's Primality Test**

Let  $N$  be an ODD INTEGER, and assume there exists a LUCAS SEQUENCE  $\{U_n\}$  with associated SYLVESTER CYCLOTOMIC NUMBERS  $\{Q_n\}$  such that there is an  $n > \sqrt{N}$  (with  $n$  and  $N$  RELATIVELY PRIME) for which  $N$  DIVIDES  $Q_n$ . Then  $N$  is a PRIME unless it has one of the following two forms:

1.  $N = (n-1)^2$ , with  $n-1$  PRIME and  $n > 4$ , or

2.  $N = n^2 - 1$ , with  $n-1$  and  $n+1$  PRIME.

see also LUCAS SEQUENCE, SYLVESTER CYCLOTOMIC NUMBER

References

**Waring's Conjecture**

see WARING'S PRIME CONJECTURE, WARING'S SUM CONJECTURE

**Waring Formula**

$$A^n + B^n = \sum_{j=0}^{\lfloor n/2 \rfloor} (-1)^j \frac{n}{n-j} \binom{n-j}{j} (AB)^j (A+B)^{n-2j},$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION and  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT.

see also FERMAT'S LAST THEOREM

**Waring's Prime Conjecture**

Every ODD INTEGER is a PRIME or the sum of three PRIMES.

**Waring's Problem**

Waring proposed a generalization of LAGRANGE'S FOUR-SQUARE THEOREM, stating that every RATIONAL INTEGER is the sum of a fixed number  $g(n)$  of  $n$ th POWERS of INTEGERS, where  $n$  is any given POSITIVE INTEGER and  $g(n)$  depends only on  $n$ . Waring originally speculated that  $g(2) = 4$ ,  $g(3) = 9$ , and  $g(4) = 19$ . In 1909, Hilbert proved the general conjecture using an identity in 25-fold multiple integrals (Rademacher and Toeplitz 1957, pp. 52–61).

In LAGRANGE'S FOUR-SQUARE THEOREM, Lagrange proved that  $g(2) = 4$ , where 4 may be reduced to 3 except for numbers of the form  $4^n(8k+7)$  (as proved by Legendre). In the early twentieth century, Dickson, Pillai, and Niven proved that  $g(3) = 9$ . Hilbert, Hardy, and Vinogradov proved  $g(4) \leq 21$ , and this was subsequently reduced to  $g(4) = 19$  by Balasubramanian et al. (1986). Liouville proved (using LAGRANGE'S FOUR-SQUARE THEOREM and LIOUVILLE POLYNOMIAL IDENTITY) that  $g(5) \leq 53$ , and this was improved to 47, 45, 41, 39, 38, and finally  $g(5) \leq 37$  by Wieferich. See Rademacher and Toeplitz (1957, p. 56) for a simple proof. J.-J. Chen (1964) proved that  $g(5) = 37$ .

Dickson, Pillai, and Niven also conjectured an explicit formula for  $g(s)$  for  $s > 6$  (Bell 1945), based on the relationship

$$\left(\frac{3}{2}\right)^n - \left\lfloor \left(\frac{3}{2}\right)^n \right\rfloor = 1 - \left(\frac{1}{2}\right)^n \left\{ \left\lfloor \left(\frac{3}{2}\right)^n + 2 \right\rfloor \right\}. \quad (1)$$

If the DIOPHANTINE (i.e.,  $n$  is restricted to being an INTEGER) inequality

$$\left\{ \left( \frac{3}{2} \right)^n \right\} \leq 1 - \left( \frac{3}{4} \right)^n \quad (2)$$

is true, then

$$g(n) = 2^n + \left\lfloor \left( \frac{3}{2} \right)^n \right\rfloor - 2. \quad (3)$$

This was given as a lower bound by Euler, and has been verified to be correct for  $6 \leq n \leq 200,000$ . Since 1957, it has been known that at most a FINITE number of  $k$  exceed Euler's lower bound.

There is also a related problem of finding the least INTEGER  $n$  such that every POSITIVE INTEGER beyond a certain point (i.e., all but a FINITE number) is the SUM of  $G(n)$   $n$ th POWERS. From 1920–1928, Hardy and Littlewood showed that

$$G(n) \leq (n-2)2^{n-1} + 5 \quad (4)$$

and conjectured that

$$G(k) < \begin{cases} 2k+1 & \text{for } k \text{ not a power of 2} \\ 4k & \text{for } k \text{ a power of 2.} \end{cases} \quad (5)$$

The best currently known bound is

$$G(k) < ck \ln k \quad (6)$$

for some constant  $c$ . Heilbronn (1936) improved Vinogradov's results to obtain

$$G(n) \leq 6n \ln n + \left[ 4 + 3 \ln \left( 3 + \frac{2}{n} \right) \right] n + 3. \quad (7)$$

It has long been known that  $G(2) = 4$ . Dickson and Landau proved that the only INTEGERS requiring nine CUBES are 23 and 239, thus establishing  $G(3) \leq 8$ . Wieferich proved that only 15 INTEGERS require eight CUBES: 15, 22, 50, 114, 167, 175, 186, 212, 213, 238, 303, 364, 420, 428, and 454, establishing  $G(3) \leq 7$ . The largest number known requiring seven CUBES is 8042. In 1933, Hardy and Littlewood showed that  $G(4) \leq 19$ , but this was improved in 1936 to 16 or 17, and shown to be exactly 16 by Davenport (1939b). Vaughan (1986) greatly improved on the method of Hardy and Littlewood, obtaining improved results for  $n \geq 5$ . These results were then further improved by Brüdern (1990), who gave  $G(5) \leq 18$ , and Wooley (1992), who gave  $G(n)$  for  $n = 6$  to 20. Vaughan and Wooley (1993) showed  $G(8) \leq 42$ .

Let  $G^+(n)$  denote the smallest number such that *almost all* sufficiently large INTEGERS are the sum of  $G^+(n)$   $n$ th POWERS. Then  $G^+(3) = 4$  (Davenport 1939a),  $G^+(4) = 15$  (Hardy and Littlewood 1925),  $G^+(8) = 32$  (Vaughan 1986), and  $G^+(16) = 64$  (Wooley 1992). If

the negatives of POWERS are permitted in addition to the powers themselves, the largest number of  $n$ th POWERS needed to represent an arbitrary integer are denoted  $eg(n)$  and  $EG(n)$  (Wright 1934, Hunter 1941, Gardner 1986). In general, these values are much harder to calculate than are  $g(n)$  and  $G(n)$ .

The following table gives  $g(n)$ ,  $G(n)$ ,  $G^+(n)$ ,  $eg(n)$ , and  $EG(n)$  for  $n \leq 20$ . The sequence of  $g(n)$  is Sloane's A002804.

$n$	$g(n)$	$G(n)$	$G^+(n)$	$eg(n)$	$EG(n)$

## Waring's Theorem

If each of two curves meets the LINE AT INFINITY in distinct, nonsingular points, and if all their intersections are finite, then if to each common point there is attached a weight equal to the number of intersections absorbed therein, the CENTER OF MASS of these points is the center of gravity of the intersections of the asymptotes.

## Watson's Formula

Let  $J_\nu(z)$  be a BESSEL FUNCTION OF THE FIRST KIND,  $Y_\nu(z)$  a BESSEL FUNCTION OF THE SECOND KIND, and  $K_\nu(z)$  a MODIFIED BESSEL FUNCTION OF THE FIRST KIND. Also let  $\Re[z] > 0$  and require  $\Re[\mu - \nu] < 1$ . Then

$$J_\mu(z)Y_\nu(z) - J_\nu(z)Y_\mu(z) = \frac{4 \sin[(\mu - \nu)\pi]}{\pi^2} \int_0^\infty K_{\nu-\mu}(2z \sinh t) e^{-(\mu+\nu)t} dt.$$

The fourth edition of Gradshteyn and Ryzhik (1979), Iyanaga and Kawada (1980), and Ito (1987) erroneously give the exponential with a PLUS SIGN. A related integral is given by

$$J_\nu(z) \frac{\partial Y_\nu(z)}{\partial \nu} - Y_\nu(z) \frac{\partial J_\nu(z)}{\partial \nu} = -\frac{4}{\pi} \int_0^\infty K_0(2z \sinh t) e^{-2\nu t} dt$$

for  $\Re[z] > 0$ .

## Watson's Theorem

$${}_3F_2 \left[ \begin{matrix} a, b, c \\ \frac{1}{2}(a+b+1), c \end{matrix} \right] = \frac{\Gamma(\frac{1}{2})\Gamma(\frac{1}{2}+c)\Gamma[\frac{1}{2}(1+a+b)]\Gamma(\frac{1}{2}-\frac{1}{2}a-\frac{1}{2}b+c)}{\Gamma[\frac{1}{2}(1+a)]\Gamma[\frac{1}{2}(1+b)]\Gamma(\frac{1}{2}-\frac{1}{2}a+c)\Gamma(\frac{1}{2}-\frac{1}{2}b+c)},$$

where  ${}_3F_2(a, b, c; d, e; z)$  is a GENERALIZED HYPERGEOMETRIC FUNCTION and  $\Gamma(z)$  is the GAMMA FUNCTION.

## Watt's Curve

A curve named after James Watt (1736–1819), the Scottish engineer who developed the steam engine (MacTutor Archive). The curve is produced by a LINKAGE of

rods connecting two wheels of equal diameter. Let the two wheels have RADIUS  $b$  and let their centers be located a distance  $2a$  apart. Further suppose that a rod of length  $2c$  is fixed at each end to the CIRCUMFERENCE of the two wheels. Let  $P$  be the MIDPOINT of the rod. Then Watt's curve  $C$  is the LOCUS of  $P$ .

The POLAR equation of Watt's curve is

$$r^2 = b^2 - (a \sin \theta \pm \sqrt{c^2 - a^2 \cos^2 \theta})^2.$$

If  $a = c$ , then  $C$  is a CIRCLE of RADIUS  $b$  with a figure of eight inside it.

### Wave Equation

The wave equation is

$$\nabla^2 \psi = \frac{1}{v^2} \frac{\partial^2 \psi}{\partial t^2}, \quad (1)$$

where  $\nabla^2$  is the LAPLACIAN.

The 1-D wave equation is

$$\frac{\partial^2 \psi}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 \psi}{\partial t^2}. \quad (2)$$

In order to specify a wave, the equation is subject to boundary conditions

$$\psi(0, t) = 0 \quad (3)$$

$$\psi(L, t) = 0, \quad (4)$$

and initial conditions

$$\psi(x, 0) = f(x) \quad (5)$$

$$\frac{\partial \psi}{\partial t}(x, 0) = g(x). \quad (6)$$

The wave equation can be solved using the so-called d'Alembert's solution, a FOURIER TRANSFORM method, or SEPARATION OF VARIABLES.

d'Alembert devised his solution in 1746, and Euler subsequently expanded the method in 1748. Let

$$\xi \equiv x - at \quad (7)$$

$$\eta \equiv x + at. \quad (8)$$

By the CHAIN RULE,

$$\frac{\partial^2 \psi}{\partial x^2} = \frac{\partial^2 \psi}{\partial \xi^2} + 2 \frac{\partial^2 \psi}{\partial \xi \partial \eta} + \frac{\partial^2 \psi}{\partial \eta^2} \quad (9)$$

$$\frac{1}{v^2} \frac{\partial^2 \psi}{\partial t^2} = \frac{\partial^2 \psi}{\partial \xi^2} - 2 \frac{\partial^2 \psi}{\partial \xi \partial \eta} + \frac{\partial^2 \psi}{\partial \eta^2}. \quad (10)$$

The wave equation then becomes

$$\frac{\partial^2 \psi}{\partial \xi \partial \eta} = 0. \quad (11)$$

Any solution of this equation is of the form

$$\psi(\xi, \eta) = f(\eta) + g(\xi) = f(x + vt) + g(x - vt), \quad (12)$$

where  $f$  and  $g$  are any functions. They represent two waveforms traveling in opposite directions,  $f$  in the NEGATIVE  $x$  direction and  $g$  in the POSITIVE  $x$  direction.

The 1-D wave equation can also be solved by applying a FOURIER TRANSFORM to each side,

$$\begin{aligned} \int_{-\infty}^{\infty} \frac{\partial^2 \psi(x, t)}{\partial x^2} e^{-2\pi i k x} dx \\ = \frac{1}{v^2} \int_{-\infty}^{\infty} \frac{\partial^2 \psi(x, t)}{\partial t^2} e^{-2\pi i k x} dx, \end{aligned} \quad (13)$$

which is given, with the help of the FOURIER TRANSFORM DERIVATIVE identity, by

$$(2\pi i k)^2 \Psi(k, t) = \frac{1}{v^2} \frac{\partial^2 \Psi(k, t)}{\partial t^2}, \quad (14)$$

where

$$\Psi(k, t) \equiv \mathcal{F}[\psi(x, t)] = \int_{-\infty}^{\infty} \psi(x, t) e^{-2\pi i k x} dx. \quad (15)$$

This has solution

$$\Psi(k, t) = A(k)e^{2\pi i k v t} + B(k)e^{-2\pi i k v t}. \quad (16)$$

Taking the inverse FOURIER TRANSFORM gives

$$\begin{aligned} \psi(x, t) &\equiv \int_{-\infty}^{\infty} \Psi(k, t) e^{2\pi i k x} dx \\ &= \int_{-\infty}^{\infty} [A(k)e^{2\pi i k v t} \\ &\quad + B(k)e^{-2\pi i k v t}] e^{-2\pi i k x} dk \\ &= \int_{-\infty}^{\infty} A(k) e^{-2\pi i k(x-vt)} dk \\ &\quad + \int_{-\infty}^{\infty} B(k) e^{-2\pi i k(x+vt)} dk \\ &= f_1(x-vt) + b(k) f_2(x+vt), \end{aligned} \quad (17)$$

where

$$f_1(u) \equiv \mathcal{F}[A(k)] = \int_{-\infty}^{\infty} A(k) e^{-2\pi i k u} dk \quad (18)$$

$$f_2(u) \equiv \mathcal{F}[B(k)] = \int_{-\infty}^{\infty} B(k) e^{-2\pi i k u} dk. \quad (19)$$

This solution is still subject to all other initial and boundary conditions.

The 1-D wave equation can be solved by SEPARATION OF VARIABLES using a trial solution

$$\psi(x, t) = X(x)T(t). \quad (20)$$

This gives

$$T \frac{d^2 X}{dx^2} = \frac{1}{v^2} X \frac{d^2 T}{dt^2} \quad (21)$$

$$\frac{1}{X} \frac{d^2 X}{dx^2} = \frac{1}{v^2} \frac{1}{T} \frac{d^2 T}{dt^2} = -k^2. \quad (22)$$

So the solution for  $X$  is

$$X(x) = C \cos(kx) + D \sin(kx). \quad (23)$$

Rewriting (22) gives

$$\frac{1}{T} \frac{d^2 T}{dt^2} = -v^2 k^2 \equiv -\omega^2, \quad (24)$$

so the solution for  $T$  is

$$T(t) = E \cos(\omega t) + F \sin(\omega t), \quad (25)$$

where  $v \equiv \omega/k$ . Applying the boundary conditions  $\psi(0, t) = \psi(L, t) = 0$  to (23) gives

$$C = 0 \quad kL = m\pi, \quad (26)$$

where  $m$  is an INTEGER. Plugging (23), (25) and (26) back in for  $\psi$  in (21) gives, for a particular value of  $m$ ,

$$\begin{aligned} \psi_m(x, t) &= [E_m \sin(\omega_m t) + F_m \cos(\omega_m t)] D_m \sin\left(\frac{m\pi x}{L}\right) \\ &\equiv [A_m \cos(\omega_m t) + B_m \sin(\omega_m t)] \sin\left(\frac{m\pi x}{L}\right). \end{aligned} \quad (27)$$

The initial condition  $\dot{\psi}(x, 0) = 0$  then gives  $B_m = 0$ , so (27) becomes

$$\psi_m(x, t) = A_m \cos(\omega_m t) \sin\left(\frac{m\pi x}{L}\right). \quad (28)$$

The general solution is a sum over all possible values of  $m$ , so

$$\psi(x, t) = \sum_{m=1}^{\infty} A_m \cos(\omega_m t) \sin\left(\frac{m\pi x}{L}\right). \quad (29)$$

Using ORTHOGONALITY of sines again,

$$\int_0^L \sin\left(\frac{l\pi x}{L}\right) \sin\left(\frac{m\pi x}{L}\right) dx = \frac{1}{2} L \delta_{lm}, \quad (30)$$

where  $\delta_{lm}$  is the KRONECKER DELTA defined by

$$\delta_{mn} \equiv \begin{cases} 1 & m = n \\ 0 & m \neq n \end{cases}, \quad (31)$$

gives

$$\begin{aligned} \int_0^L \psi(x, 0) \sin\left(\frac{m\pi x}{L}\right) dx \\ &= \sum_{l=1}^{\infty} A_l \sin\left(\frac{l\pi x}{L}\right) \sin\left(\frac{m\pi x}{L}\right) dx \\ &= \sum_{l=1}^{\infty} A_l \frac{1}{2} L \delta_{lm} = \frac{1}{2} L A_m, \end{aligned} \quad (32)$$

so we have

$$A_m = \frac{2}{L} \int_0^L \psi(x, 0) \sin\left(\frac{m\pi x}{L}\right) dx. \quad (33)$$

The computation of  $A_m$ s for specific initial distortions is derived in the FOURIER SINE SERIES section. We already have found that  $B_m = 0$ , so the equation of motion for the string (29), with

$$\omega_m \equiv vk_m = \frac{vm\pi}{L}, \quad (34)$$

is

$$\psi(x, t) = \sum_{m=1}^{\infty} A_m \cos\left(\frac{vm\pi t}{L}\right) \sin\left(\frac{m\pi x}{L}\right), \quad (35)$$

where the  $A_m$  COEFFICIENTS are given by (33).

A damped 1-D wave

$$\frac{\partial^2 \psi}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 \psi}{\partial t^2} + b \frac{\partial \psi}{\partial t}, \quad (36)$$

given boundary conditions

$$\psi(0, t) = 0 \quad (37)$$

$$\psi(L, t) = 0, \quad (38)$$

initial conditions

$$\psi(x, 0) = f(x) \quad (39)$$

$$\frac{\partial \psi}{\partial t}(x, 0) = g(x), \quad (40)$$

and the additional constraint

$$0 < b < \frac{2\pi}{Lv}, \quad (41)$$

can also be solved as a FOURIER SERIES.

$\psi(x, t)$

$$= \sum_{n=1}^{\infty} \sin\left(\frac{n\pi x}{L}\right) e^{-v^2 b t/2} [a_n \sin(\mu_n t) + b_n \cos(\mu_n t)], \quad (42)$$

where

$$\mu_n \equiv \frac{\sqrt{4v^2 n^2 \pi^2 - b^2 L^2 v^4}}{2L} = \frac{v\sqrt{4n^2 \pi^2 - b^2 L^2 v^2}}{2L} \quad (43)$$

$$b_n = \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) f(x) dx \quad (44)$$

$$a_n = \frac{2}{L\mu_n} \left\{ \int_0^L \sin\left(\frac{n\pi x}{L}\right) \left[ g(x) + \frac{v^2 b}{2} f(x) \right] dx \right\} \quad (45)$$

To find the motion of a rectangular membrane with sides of length  $L_x$  and  $L_y$  (in the absence of gravity), use the 2-D wave equation

$$\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} = \frac{1}{v^2} \frac{\partial^2 z}{\partial t^2}, \quad (46)$$

where  $z(x, y, t)$  is the vertical displacement of a point on the membrane at position  $(x, y)$  and time  $t$ . Use SEPARATION OF VARIABLES to look for solutions of the form

$$z(x, y, t) = X(x)Y(y)T(t). \quad (47)$$

Plugging (47) into (46) gives

$$YT \frac{d^2 X}{dx^2} + XT \frac{d^2 Y}{dy^2} = \frac{1}{v^2} XY \frac{d^2 T}{dt^2}, \quad (48)$$

where the partial derivatives have now become complete derivatives. Multiplying (48) by  $v^2/XYT$  gives

$$\frac{v^2}{X} \frac{d^2 X}{dx^2} + \frac{v^2}{Y} \frac{d^2 Y}{dy^2} = \frac{1}{T} \frac{d^2 T}{dt^2}. \quad (49)$$

The left and right sides must both be equal to a constant, so we can separate the equation by writing the right side as

$$\frac{1}{T} \frac{d^2 T}{dt^2} = -\omega^2. \quad (50)$$

This has solution

$$T(t) = C_\omega \cos(\omega t) + D_\omega \sin(\omega t). \quad (51)$$

Plugging (50) back into (49),

$$\frac{v^2}{X} \frac{d^2 X}{dx^2} + \frac{v^2}{Y} \frac{d^2 Y}{dy^2} = -\omega^2, \quad (52)$$

which we can rewrite as

$$\frac{1}{X} \frac{d^2 X}{dx^2} = -\frac{1}{Y} \frac{d^2 Y}{dy^2} - \frac{\omega^2}{v^2} = -k_x^2 \quad (53)$$

since the left and right sides again must both be equal to a constant. We can now separate out the  $Y(y)$  equation

$$\frac{1}{Y} \frac{d^2 Y}{dy^2} = k_x^2 - \frac{\omega^2}{v^2} \equiv -k_y^2, \quad (54)$$

where we have defined a new constant  $k_y$  satisfying

$$k_x^2 + k_y^2 = \frac{\omega^2}{v^2}. \quad (55)$$

Equations (53) and (54) have solutions

$$X(x) = E \cos(k_x x) + F \sin(k_x x) \quad (56)$$

$$Y(y) = G \cos(k_y y) + H \sin(k_y y). \quad (57)$$

We now apply the boundary conditions to (56) and (57). The conditions  $z(0, y, t) = 0$  and  $z(x, 0, t) = 0$  mean that

$$E = 0 \quad G = 0. \quad (58)$$

Similarly, the conditions  $z(L_x, y, t) = 0$  and  $z(x, L_y, t) = 0$  give  $\sin(k_x L_x) = 0$  and  $\sin(k_y L_y) = 0$ , so  $L_x k_x = p\pi$  and  $L_y k_y = q\pi$ , where  $p$  and  $q$  are INTEGERS. Solving for the allowed values of  $k_x$  and  $k_y$  then gives

$$k_x = \frac{p\pi}{L_x} \quad k_y = \frac{q\pi}{L_y}. \quad (59)$$

Plugging (52), (56), (57), (58), and (59) back into (22) gives the solution for particular values of  $p$  and  $q$ ,

$$z_{pq}(x, y, t) = [C_\omega \cos(\omega t) + D_\omega \sin(\omega t)] \times \left[ F_p \sin\left(\frac{p\pi x}{L_x}\right) \right] \left[ H_q \sin\left(\frac{q\pi y}{L_y}\right) \right]. \quad (60)$$

Lumping the constants together by writing  $A_{pq} \equiv C_\omega F_p H_q$  (we can do this since  $\omega$  is a function of  $p$  and  $q$ , so  $C_\omega$  can be written as  $C_{pq}$ ) and  $B_{pq} \equiv D_\omega F_p H_q$ , we obtain

$$z_{pq}(x, y, t) = [A_{pq} \cos(\omega_{pq}t) + B_{pq} \sin(\omega_{pq}t)] \times \sin\left(\frac{p\pi x}{L_x}\right) \sin\left(\frac{q\pi y}{L_y}\right). \quad (61)$$

Plots of the spatial part for modes (1, 1), (1, 2), (2, 1), and (2, 2) follow.

The general solution is a sum over all possible values of  $p$  and  $q$ , so the final solution is

$$z(x, y, t) = \sum_{p=1}^{\infty} \sum_{q=1}^{\infty} [A_{pq} \cos(\omega_{pq}t) + B_{pq} \sin(\omega_{pq}t)] \times \sin\left(\frac{p\pi x}{L_x}\right) \sin\left(\frac{q\pi y}{L_y}\right), \quad (62)$$

where  $\omega$  is defined by combining (55) and (59) to yield

$$\omega_{pq} = \pi v \sqrt{\left(\frac{p}{L_x}\right)^2 + \left(\frac{q}{L_y}\right)^2}. \quad (63)$$

Given the initial conditions  $z(x, y, 0)$  and  $\frac{\partial z}{\partial t}(x, y, 0)$ , we can compute the  $A_{pq}$ s and  $B_{pq}$ s explicitly. To accomplish this, we make use of the orthogonality of the SINE function in the form

$$I \equiv \int_0^L \sin\left(\frac{m\pi x}{L}\right) \sin\left(\frac{n\pi x}{L}\right) dx = \frac{1}{2} L \delta_{mn}, \quad (64)$$

where  $\delta_{mn}$  is the KRONECKER DELTA. This can be demonstrated by direct INTEGRATION. Let  $u \equiv \pi x/L$  so  $du = (\pi/L) dx$  in (64), then

$$I = \frac{L}{\pi} \int_0^\pi \sin(mu) \sin(nu) du. \quad (65)$$

Now use the trigonometric identity

$$\sin \alpha \sin \beta = \frac{1}{2} [\cos(\alpha - \beta) - \cos(\alpha + \beta)] \quad (66)$$

to write

$$I = \frac{L}{2\pi} \int_0^\pi \cos[(m-n)u] du + \int_0^\pi \cos[(m+n)u] du. \quad (67)$$

Note that for an INTEGER  $l \neq 0$ , the following INTEGRAL vanishes

$$\begin{aligned} \int_0^\pi \cos(lu) du &= \frac{1}{l} [\sin(lu)]_0^\pi = \frac{1}{l} [\sin(l\pi) - \sin 0] \\ &= \frac{1}{l} \sin(l\pi) = 0, \end{aligned} \quad (68)$$

since  $\sin(l\pi) = 0$  when  $l$  is an INTEGER. Therefore,  $I = 0$  when  $l \equiv m - n \neq 0$ . However,  $I$  does *not* vanish when  $l = 0$ , since

$$\int_0^\pi \cos(0 \cdot u) du = \int_0^\pi du = \pi. \quad (69)$$

We therefore have that  $I = L\delta_{mn}/2$ , so we have derived (64). Now we multiply  $z(x, y, 0)$  by two sine terms and integrate between 0 and  $L_x$  and between 0 and  $L_y$ ,

$$I = \int_0^{L_y} \left[ \int_0^{L_x} z(x, y, 0) \sin\left(\frac{p\pi x}{L_x}\right) dx \right] \times \sin\left(\frac{q\pi y}{L_y}\right) dy. \quad (70)$$

Now plug in  $z(x, y, t)$ , set  $t = 0$ , and prime the indices to distinguish them from the  $p$  and  $q$  in (70),

$$\begin{aligned} I &= \sum_{q'=1}^{\infty} \int_0^{L_y} \left[ \sum_{p'=1}^{\infty} A_{p'q'} \int_0^{L_x} \sin\left(\frac{p'\pi x}{L_x}\right) \sin\left(\frac{p\pi x}{L_x}\right) dx \right] \\ &\quad \times \sin\left(\frac{q\pi y}{L_y}\right) \sin\left(\frac{q'\pi y}{L_y}\right) dy. \end{aligned} \quad (71)$$

Making use of (64) in (71),

$$\begin{aligned} I &= \sum_{q'=1}^{\infty} \int_0^{L_y} \sum_{p'=1}^{\infty} A_{p'q'} \frac{L_x}{2} \delta_{p,p'} \\ &\quad \times \sin\left(\frac{q\pi y}{L_y}\right) \sin\left(\frac{q'\pi y}{L_y}\right) dy, \end{aligned} \quad (72)$$

so the sums over  $p'$  and  $q'$  collapse to a single term

$$I = \frac{L_x}{2} \sum_{q=1}^{\infty} A_{pq} \frac{L_y}{2} \delta_{q,q} = \frac{L_x L_y}{4} A_{pq}. \quad (73)$$

Equating (72) and (73) and solving for  $A_{pq}$  then gives

$$\begin{aligned} A_{pq} &= \frac{4}{L_x L_y} \int_0^{L_y} \left[ \int_0^{L_x} z(x, y, 0) \sin\left(\frac{p\pi x}{L_x}\right) dx \right] \\ &\quad \times \sin\left(\frac{q\pi y}{L_y}\right) dy. \end{aligned} \quad (74)$$

An analogous derivation gives the  $B_{pq}$ s as

$$B_{pq} = \frac{4}{\omega_{pq} L_x L_y} \int_0^{L_y} \left[ \int_0^{L_x} \frac{\partial z}{\partial t}(x, y, 0) \sin\left(\frac{p\pi x}{L_x}\right) dx \right] \times \sin\left(\frac{q\pi y}{L_y}\right) dy. \quad (75)$$

The equation of motion for a membrane shaped as a RIGHT ISOSCELES TRIANGLE of length  $c$  on a side and with the sides oriented along the POSITIVE  $x$  and  $y$  axes is given by

$$\psi(x, y, t) = [C_{pq} \cos(\omega_{pq} t) + D_{pq} \sin(\omega_{pq} t)] \times \left[ \sin\left(\frac{p\pi x}{c}\right) \sin\left(\frac{q\pi y}{c}\right) - \sin\left(\frac{q\pi x}{c}\right) \sin\left(\frac{p\pi y}{c}\right) \right], \quad (76)$$

where

$$\omega_{pq} = \frac{\pi v}{c} \sqrt{p^2 + q^2} \quad (77)$$

and  $p, q$  INTEGERS with  $p > q$ . This solution can be obtained by subtracting two wave solutions for a square membrane with the indices reversed. Since points on the diagonal which are equidistant from the center must have the same wave equation solution (by symmetry), this procedure gives a wavefunction which will vanish along the diagonal as long as  $p$  and  $q$  are both EVEN or ODD. We must further restrict the modes since those with  $p < q$  give wavefunctions which are just the NEGATIVE of  $(q, p)$  and  $(p, p)$  give an identically zero wavefunction. The following plots show (3, 1), (4, 2), (5, 1), and (5, 3).

### Wave Operator

An OPERATOR relating the asymptotic state of a DYNAMICAL SYSTEM governed by the Schrödinger equation

$$i \frac{d}{dt} \psi(t) = H \psi(t)$$

to its original asymptotic state.

see also SCATTERING OPERATOR

### Wave Surface

A SURFACE represented parametrically by ELLIPTIC FUNCTIONS.

### Wavelet

Wavelets are a class of functions used to localize a given function in both space and scaling. A family of wavelets can be constructed from a function  $\psi(x)$ , sometimes known as a "mother wavelet," which is confined in a finite interval. "Daughter wavelets"  $\psi^{a,b}(x)$  are then formed by translation ( $b$ ) and contraction ( $a$ ). Wavelets are especially useful for compressing image data, since a WAVELET TRANSFORM has properties which are in some ways superior to a conventional FOURIER TRANSFORM.

An individual wavelet can be defined by

$$\psi^{a,b}(x) = |a|^{-1/2} \psi\left(\frac{x-b}{a}\right). \quad (1)$$

Then

$$W_\psi(f)(a, b) = \frac{1}{\sqrt{a}} \int_{-\infty}^{\infty} f(t) \psi\left(\frac{t-b}{a}\right) dt, \quad (2)$$

and CALDERÓN'S FORMULA gives

$$f(x) = C_\psi \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \langle f, \psi^{a,b} \rangle \psi^{a,b}(x) a^{-2} da db. \quad (3)$$

A common type of wavelet is defined using HAAR FUNCTIONS.

## Wavelet Matrix

A MATRIX composed of HAAR FUNCTIONS which is used in the WAVELET TRANSFORM. The fourth-order wavelet matrix is given by

$$\begin{aligned}
 W_4 &= \begin{bmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & -1 & 0 \\ 1 & -1 & 0 & 1 \\ 1 & -1 & 0 & -1 \end{bmatrix} \\
 &= \begin{bmatrix} 1 & 1 & & \\ 1 & -1 & & \\ & & 1 & 1 \\ & & 1 & -1 \end{bmatrix} \begin{bmatrix} 1 & & & \\ & 1 & & \\ & & 1 & 0 \\ & & & 0 \end{bmatrix} \\
 &\quad \times \begin{bmatrix} 1 & 1 & & \\ 1 & -1 & & \\ & & 1 & \\ & & & 1 \end{bmatrix}.
 \end{aligned}$$

A wavelet matrix can be computed in  $\mathcal{O}(n)$  steps, compared to  $\mathcal{O}(n \lg 2)$  for the FOURIER MATRIX.

see also FOURIER MATRIX, WAVELET, WAVELET TRANSFORM

## Wavelet Transform

A transform which localizes a function both in space and scaling and has some desirable properties compared to the FOURIER TRANSFORM. The transform is based on a WAVELET MATRIX, which can be computed more quickly than the analogous FOURIER MATRIX.

## Weak Convergence

Weak convergence is usually either denoted  $x_n \xrightarrow{w} x$  or  $x_n \rightharpoonup x$ . A SEQUENCE  $\{x_n\}$  of VECTORS in an INNER PRODUCT SPACE  $E$  is called weakly convergent to a VECTOR in  $E$  if

$$\langle x_n, y \rangle \rightarrow \langle x, y \rangle \quad \text{as } n \rightarrow \infty, \quad \text{for all } y \in E.$$

Every STRONGLY CONVERGENT sequence is also weakly convergent (but the opposite does not usually hold). This can be seen as follows. Consider the sequence  $\{x_n\}$  that converges strongly to  $x$ , i.e.,  $\|x_n - x\| \rightarrow 0$  as  $n \rightarrow \infty$ . SCHWARZ'S INEQUALITY now gives

$$|\langle x_n - x, y \rangle| \leq \|x_n - x\| \|y\| \quad \text{as } n \rightarrow \infty.$$

The definition of weak convergence is therefore satisfied. see also INNER PRODUCT SPACE, SCHWARZ'S INEQUALITY, STRONG CONVERGENCE

## Weak Law of Large Numbers

Also known as BERNOULLI'S THEOREM. Let  $x_1, \dots, x_n$  be a sequence of independent and identically distributed random variables, each having a MEAN  $\langle x_i \rangle = \mu$  and STANDARD DEVIATION  $\sigma$ . Define a new variable

$$x \equiv \frac{x_1 + \dots + x_n}{n}. \quad (1)$$

Then, as  $n \rightarrow \infty$ , the sample mean  $\langle x \rangle$  equals the population MEAN  $\mu$  of each variable.

$$\langle x \rangle = \left\langle \frac{x_1 + \dots + x_n}{n} \right\rangle = \frac{1}{n} (\langle x_1 \rangle + \dots + \langle x_n \rangle) = \frac{n\mu}{n} = \mu \quad (2)$$

$$\begin{aligned}
 \text{var}(x) &= \text{var} \left( \frac{x_1 + \dots + x_n}{n} \right) \\
 &= \text{var} \left( \frac{x_1}{n} \right) + \dots + \text{var} \left( \frac{x_n}{n} \right) \\
 &= \frac{\sigma^2}{n^2} + \dots + \frac{\sigma^2}{n^2} = \frac{\sigma^2}{n}.
 \end{aligned} \quad (3)$$

Therefore, by the CHEBYSHEV INEQUALITY, for all  $\epsilon > 0$ ,

$$P(|x - \mu| \geq \epsilon) \leq \frac{\text{var}(x)}{\epsilon^2} = \frac{\sigma^2}{n\epsilon^2}. \quad (4)$$

As  $n \rightarrow \infty$ , it then follows that

$$\lim_{n \rightarrow \infty} P(|x - \mu| \geq \epsilon) = 0 \quad (5)$$

for  $\epsilon$  arbitrarily small; i.e., as  $n \rightarrow \infty$ , the sample MEAN is the same as the population MEAN.

Stated another way, if an event occurs  $x$  times in  $s$  TRIALS and if  $p$  is the probability of success in a single TRIAL, then the probability that the relative frequency of successes is  $x/s$  differs from  $p$  by less than any arbitrary POSITIVE quantity  $\epsilon$  which approaches 1 as  $s \rightarrow \infty$ .

see also LAW OF TRULY LARGE NUMBERS, STRONG LAW OF LARGE NUMBERS

### Weakly Binary Tree

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

A ROOTED TREE for which the ROOT is adjacent to at most two VERTICES, and all nonroot VERTICES are adjacent to at most three VERTICES. Let  $b(n)$  be the number of weakly binary trees of order  $n$ , then  $b(5) = 6$ . Let

$$g(z) = \sum_{i=0}^{\infty} g_i z^i, \quad (1)$$

where

$$g_0 = 0 \quad (2)$$

$$g_1 = g_2 = g_3 = 1 \quad (3)$$

$$g_{2i+1} = \sum_{j=1}^i g_{2i+1-j} g_j \quad (4)$$

$$g_{2i} = \frac{1}{2} g_i (g_i + 1) + \sum_{j=1}^{i-1} g_{2i-j} g_j. \quad (5)$$

Otter (Otter 1948, Harary and Palmer 1973, Knuth 1969) showed that

$$\lim_{n \rightarrow \infty} \frac{b(n)n^{3/2}}{\xi^n} = \eta, \quad (6)$$

where

$$\xi = 2.48325 \dots \quad (7)$$

is the unique POSITIVE ROOT of

$$g\left(\frac{1}{x}\right) = 1,$$

and

$$\eta = 0.7916032 \dots \quad (8)$$

$\xi$  is also given by

$$\xi = \lim_{n \rightarrow \infty} (c_n)^{2^{-n}}, \quad (9)$$

where  $c_n$  is given by

$$c_0 = 2 \quad (10)$$

$$c_n = (c_{n-1})^2 + 2, \quad (11)$$

giving

$$\eta = \frac{1}{2} \sqrt{\frac{\xi}{\pi}} \sqrt{3 + \frac{1}{c_1} + \frac{1}{c_1 c_2} + \frac{1}{c_1 c_2 c_3} + \dots} \quad (12)$$

### Weakly Complete Sequence

A SEQUENCE of numbers  $V = \{\nu_n\}$  is said to be weakly complete if every POSITIVE INTEGER  $n$  beyond a certain point  $N$  is the sum of some SUBSEQUENCE of  $V$  (Honsberger 1985). Dropping two terms from the FIBONACCI NUMBERS produces a SEQUENCE which is not even weakly complete. However, the SEQUENCE

$$F'_n \equiv F_n - (-1)^n$$

is weakly complete, even with any finite subsequence deleted (Graham 1964).

### Weakly Independent

An infinite sequence  $\{a_i\}$  of POSITIVE INTEGERS is called weakly independent if any relation  $\sum \epsilon_i a_i$  with  $\epsilon_i = 0$  or  $\pm 1$  and  $\epsilon_i = 0$ , except finitely often, IMPLIES  $\epsilon_i = 0$  for all  $i$ .

**Weber Differential Equations**

Consider the differential equation satisfied by

$$w = z^{-1/2} W_{k, -1/4}(\tfrac{1}{2} z^2), \quad (1)$$

where  $W$  is a WHITTAKER FUNCTION.

$$\frac{d}{z dz} \left[ \frac{d(w z^{1/2})}{z dz} \right] + \left( -\frac{1}{4} + \frac{2k}{z^2} + \frac{3}{4z^4} \right) w z^{1/2} = 0 \quad (2)$$

$$\frac{d^2 w}{dz^2} + (2k - \tfrac{1}{4} z^2) w = 0. \quad (3)$$

This is usually rewritten

$$\frac{d^2 D_n(z)}{dz^2} + (n + \tfrac{1}{2} - \tfrac{1}{4} z^2) D_n(z) = 0. \quad (4)$$

The solutions are PARABOLIC CYLINDER FUNCTIONS.

The equations

$$\frac{d^2 U}{du^2} - (c + k^2 u^2) U = 0 \quad (5)$$

$$\frac{d^2 V}{dv^2} + (c - k^2 v^2) V = 0, \quad (6)$$

which arise by separating variables in LAPLACE'S EQUATION in PARABOLIC CYLINDRICAL COORDINATES, are also known as the Weber differential equations. As above, the solutions are known as PARABOLIC CYLINDER FUNCTIONS.

**Weber's Discontinuous Integrals**

$$\int_0^\infty J_0(ax) \cos(cx) dx = \begin{cases} 0 & a < c \\ \frac{1}{\sqrt{a^2 - c^2}} & a > c \end{cases}$$

$$\int_0^\infty J_0(ax) \sin(cx) dx = \begin{cases} \frac{1}{\sqrt{c^2 - a^2}} & a < c \\ 0 & a > c, \end{cases}$$

where  $J_0(z)$  is a zeroth order BESSEL FUNCTION OF THE FIRST KIND.

**References**

Bowman, F. *Introduction to Bessel Functions*. New York: Dover, pp. 59–60, 1958.

**Weber's Formula**

$$\begin{aligned} \frac{1}{2p^2} e^{-(a^2+b^2)/(4p^2)} I_\nu \left( \frac{ab}{2p^2} \right) \\ = \int_0^\infty e^{-p^2 t^2} J_\nu(at) J_\nu(bt) t dt, \end{aligned}$$

where  $\Re[\nu] > -1$ ,  $|\arg p| < \pi/4$ , and  $a, b > 0$ ,  $J_\nu(z)$  is a BESSEL FUNCTION OF THE FIRST KIND, and  $I_\nu(z)$  is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND.

see also BESSEL FUNCTION OF THE FIRST KIND, MODIFIED BESSEL FUNCTION OF THE FIRST KIND

**References**

**Weber Functions**

Although BESSEL FUNCTIONS OF THE SECOND KIND are sometimes called Weber functions, Abramowitz and Stegun (1972) define a separate Weber function as

$$\mathcal{E}_\nu(z) = \frac{1}{\pi} \int_0^\pi \sin(\nu\theta - z \sin \theta) d\theta. \quad (1)$$

Letting  $\zeta_n = e^{2\pi i/n}$  be a ROOT OF UNITY, another set of Weber functions is defined as

$$f(z) = \frac{\eta(\frac{1}{2}(z+1))}{\zeta_{48} \eta(z)} \quad (2)$$

$$f_1(z) = \frac{\eta(\frac{1}{2}z)}{\eta(z)} \quad (3)$$

$$f_2(z) = \sqrt{2} \frac{\eta(2z)}{\eta(z)} \quad (4)$$

$$\gamma_2 = \frac{f^{24}(z) - 16}{f^8(z)} \quad (5)$$

$$\gamma_3 = \frac{[f^{24}(z) + 8][f_1^8(z) - f_2^8(z)]}{f^8(z)} \quad (6)$$

(Weber 1902, Atkin and Morain 1993), where  $\eta(z)$  is the DEDEKIND ETA FUNCTION. The Weber functions satisfy the identities

$$f(z+1) = \frac{f_1(z)}{\zeta_{48}} \quad (7)$$

$$f_1(z+1) = \frac{f(z)}{\zeta_{48}} \quad (8)$$

$$f_2(z+1) = \zeta_{24} f_2(z) \quad (9)$$

$$f\left(-\frac{1}{z}\right) = f(z) \quad (10)$$

$$f_1\left(-\frac{1}{z}\right) = f_2(z) \quad (11)$$

$$f_2\left(-\frac{1}{z}\right) = f_1(z) \quad (12)$$

(Weber 1902, Atkin and Morain 1993).

**Wedge Product**

An antisymmetric operation on DIFFERENTIAL FORMS (also called the EXTERIOR DERIVATIVE)

$$dx_i \wedge dx_j = -dx_j \wedge dx_i, \quad (1)$$

which IMPLIES

$$dx_i \wedge dx_i = 0 \quad (2)$$

$$b_i \wedge dx_j = dx_j \wedge b_i = b_i dx_j \quad (3)$$

$$dx_i \wedge (b_i dx_j) = b_i dx_i \wedge dx_j \quad (4)$$

$$\begin{aligned} \theta_1 \wedge \theta_2 &= (b_1 dx_1 + b_2 dx_2) \wedge (c_1 dx_1 + c_2 dx_2) \\ &= (b_1 c_2 - b_2 c_1) dx_1 \wedge dx_2 \\ &= -\theta_2 \wedge \theta_1. \end{aligned} \quad (5)$$

The wedge product is ASSOCIATIVE

$$(s \wedge t) \wedge u = s \wedge (t \wedge u), \quad (6)$$

and BILINEAR

$$(\alpha_1 s_1 + \alpha_2 s_2) \wedge t = \alpha_1 (s_1 \wedge t) + \alpha_2 (s_2 \wedge t) \quad (7)$$

$$s \wedge (\alpha_1 t_1 + \alpha_2 t_2) = \alpha_1 (s \wedge t_1) + \alpha_2 (s \wedge t_2), \quad (8)$$

but not (in general) COMMUTATIVE

$$s \wedge t = (-1)^{pq} (t \wedge s), \quad (9)$$

where  $s$  is a  $p$ -form and  $t$  is a  $q$ -form. For a 0-form  $s$  and 1-form  $t$ ,

$$(s \wedge t)_\mu = s t_\mu. \quad (10)$$

For a 1-form  $s$  and 1-form  $t$ ,

$$(s \wedge t)_{\mu\nu} = \frac{1}{2} (s_\mu t_\nu - s_\nu t_\mu). \quad (11)$$

The wedge product is the "correct" type of product to use in computing a VOLUME ELEMENT

$$dV = dx_1 \wedge \dots \wedge dx_n. \quad (12)$$

see also DIFFERENTIAL FORM, EXTERIOR DERIVATIVE, INNER PRODUCT, VOLUME ELEMENT

**Weekday**

The day of the week  $W$  for a given day of the month  $D$ , month  $M$ , and year  $100C + Y$  can be determined from the simple equation

$$W \equiv D + [2.6M - 0.2] + \left[\frac{1}{4}Y\right] + \left[\frac{1}{4}C\right] - 2C \pmod{7},$$

where months are numbered beginning with March and  $W = 0$  for Sunday,  $W = 1$  for Monday, etc. (Uspensky and Heaslet 1939, Vardi 1991).

A more complicated form is given by

$$W \equiv D + M + C + Y \pmod{7},$$

where  $W = 1$  for Sunday,  $W = 2$  for Monday, etc. and the numbers assigned to months, centuries, and years are given in the tables below (Kraitchik 1942, pp. 110–111).

Month	$M$

#### Weibull Distribution

The Weibull distribution is given by

$$P(x) = \alpha\beta^{-\alpha}x^{\alpha-1}e^{-(x/\beta)^\alpha} \quad (1)$$

$$D(x) = 1 - e^{-(x/\beta)^\alpha} \quad (2)$$

for  $x \in [0, \infty)$  (*Mathematica*<sup>®</sup> Statistics' Continuous Distributions' WeibullDistribution[a,b], Wolfram Research, Champaign, IL). The MEAN, VARIANCE, SKEWNESS, and KURTOSIS of this distribution are

$$\mu = \beta\Gamma(1 + \alpha^{-1}) \quad (3)$$

$$\sigma^2 = \beta^2[\Gamma(1 + 2\alpha^{-1}) - \Gamma^2(1 + \alpha^{-1})] \quad (4)$$

$$\gamma_1 = \frac{2\Gamma^3(1 + \alpha^{-1}) - 3\Gamma(1 + \alpha^{-1})\Gamma(1 + 2\alpha^{-1})}{[\Gamma(1 + 2\alpha^{-1}) - \Gamma^2(1 + \alpha^{-1})]^{3/2}}$$

$$+ \frac{\Gamma(1 + 3\alpha^{-1})}{[\Gamma(1 + 2\alpha^{-1}) - \Gamma^2(1 + \alpha^{-1})]^{3/2}} \quad (5)$$

$$\gamma_2 = \frac{f(a)}{[\Gamma(1 + 2\alpha^{-1}) - \Gamma^2(1 + \alpha^{-1})]^2}, \quad (6)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION and

$$f(a) \equiv -6\Gamma^4(1 + \alpha^{-1}) + 12\Gamma^2(1 + \alpha^{-1})\Gamma(1 + 2\alpha^{-1}) - 3\Gamma^2(1 + 2\alpha^{-1}) - 4\Gamma(1 + \alpha^{-1})\Gamma(1 + 3\alpha^{-1}) + \Gamma(1 + 4\alpha^{-1}). \quad (7)$$

A slightly different form of the distribution is

$$P(x) = \frac{\alpha}{\beta}x^{\alpha-1}e^{-x^\alpha/\beta} \quad (8)$$

$$D(x) = 1 - e^{-x^\alpha/\beta} \quad (9)$$

(Mendenhall and Sincich 1995). The MEAN and VARIANCE for this form are

$$\mu = \beta^{1/\alpha}\Gamma(1 + \alpha^{-1}) \quad (10)$$

$$\sigma^2 = \beta^{2/\alpha}[\Gamma(1 + 2\alpha^{-1}) - \Gamma^2(1 + \alpha^{-1})]. \quad (11)$$

The Weibull distribution gives the distribution of lifetimes of objects. It was originally proposed to quantify fatigue data, but it is also used in analysis of systems involving a "weakest link."

#### Weierstraß Approximation Theorem

If  $f$  is continuous on  $[a, b]$ , then there exists a POLYNOMIAL  $p$  on  $[a, b]$  such that

$$|f(x) - P(x)| < \epsilon$$

for all  $x \in [a, b]$  and  $\epsilon > 0$ . In words, any continuous function on a closed and bounded interval can be uniformly approximated on that interval by POLYNOMIALS to any degree of accuracy.

see also MÜNTZ'S THEOREM

#### Weierstraß-Casorati Theorem

An ANALYTIC FUNCTION approaches any given value arbitrarily closely in any  $\epsilon$ -NEIGHBORHOOD of an ESSENTIAL SINGULARITY.

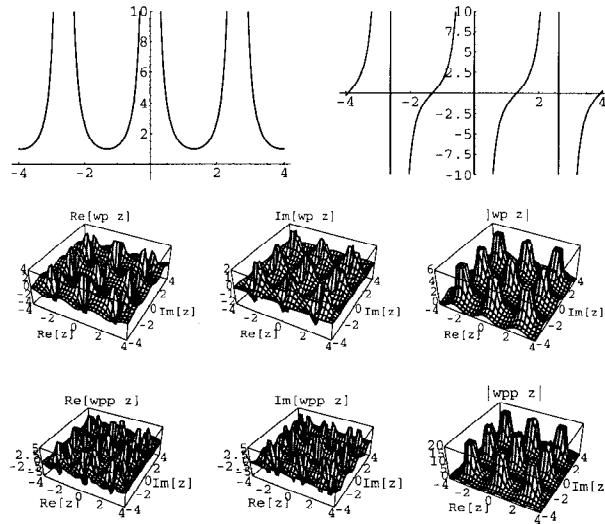

## Weierstraß Constant

$$\begin{aligned}\sigma\left(\frac{1}{2}\right) &= \frac{1}{2} \prod_{\substack{(m,n) \neq \\ (0,0)}} \left[1 - \frac{1}{2(m+ni)}\right] \\ &\quad \times e^{1/[2(m+ni)] + 1/[8(m+ni)^2]} \\ &= \frac{2^{5/4} \sqrt{\pi} e^{\pi/8}}{\Gamma^2\left(\frac{1}{4}\right)} = 0.4749493799 \dots\end{aligned}$$

## Weierstraß Elliptic Function

The Weierstraß elliptic functions are elliptic functions which, unlike the JACOBI ELLIPTIC FUNCTIONS, have a second-order POLE at  $z = 0$ . The above plots show the Weierstraß elliptic function  $\wp(z)$  and its derivative  $\wp'(z)$  for invariants (defined below) of  $g_2 = 0$  and  $g_3 = 0$ . Weierstraß elliptic functions are denoted  $\wp(z)$  and can be defined by

$$\wp(z) = \frac{1}{z^2} + \sum_{m,n=-\infty}^{\infty} \left[ \frac{1}{(z - 2m\omega_1 - 2n\omega_2)^2} - \frac{1}{(2m\omega_1 + 2n\omega_2)^2} \right]. \quad (1)$$

Write  $\Omega_{mn} \equiv 2m\omega_1 + 2n\omega_2$ . Then this can be written

$$\wp(z) = z^{-2} + \sum_{m,n}' [(z - \Omega_{mn})^{-2} - \Omega_{mn}^{-2}]. \quad (2)$$

## Weierstraß Elliptic Function

An equivalent definition which converges more rapidly is

$$\wp(z) = \left(\frac{\pi}{2\omega_1}\right)^2 \left[ -\frac{1}{3} + \sum_{n=-\infty}^{\infty} \csc^2 \left( \frac{z - 2n\omega_2}{2\omega_1} \pi \right) - \sum_{n=-\infty}' \csc^2 \left( \frac{n\omega_2}{\omega_1} \pi \right) \right]. \quad (3)$$

$\wp(z)$  is an EVEN FUNCTION since  $\wp(-z)$  gives the same terms in a different order. To specify  $\wp$  completely, its periods or invariants, written  $\wp(z|\omega_1, \omega_2)$  and  $\wp(z; g_2, g_3)$ , respectively, must also be specified.

The differential equation from which Weierstraß elliptic functions arise can be found by expanding about the origin the function  $f(z) \equiv \wp(z) - z^{-2}$ .

$$\begin{aligned}\wp(z) - z^{-2} &= f(0) + f'(0)z + \frac{1}{2!}f''(0)z^2 \\ &\quad + \frac{1}{3!}f'''(0)z^3 + \frac{1}{4!}f^{(4)}(0)z^4 + \dots\end{aligned} \quad (4)$$

But  $f(0) = 0$  and the function is even, so  $f'(0) = f'''(0) = 0$  and

$$f(z) = \wp(z) - z^{-2} = \frac{1}{2!}f''(0)z^2 + \frac{1}{4!}f^{(4)}(0)z^4 + \dots \quad (5)$$

Taking the derivatives

$$f' = -2\Sigma'[(z - \Omega_{mn})^{-3}] \quad (6)$$

$$f'' = 6\Sigma'(z - \Omega_{mn})^{-4} \quad (7)$$

$$f''' = -24\Sigma'(z - \Omega_{mn})^{-5} \quad (8)$$

$$f^{(4)} = 120\Sigma'(z - \Omega_{mn})^{-6}. \quad (9)$$

So

$$f''(0) = 6\Sigma'\Omega_{mn}^{-4} \quad (10)$$

$$f^{(4)}(0) = 120\Sigma'\Omega_{mn}^{-6}. \quad (11)$$

Plugging in,

$$\wp(z) - z^{-2} = 3\Sigma'\Omega_{mn}^{-4}z^2 + 5\Sigma'\Omega_{mn}^{-6}z^4 + \mathcal{O}(z^6). \quad (12)$$

Define the INVARIANTS

$$g_2 \equiv 60\Sigma'\Omega_{mn}^{-4} \quad (13)$$

$$g_3 \equiv 140\Sigma'\Omega_{mn}^{-6}, \quad (14)$$

then

$$\wp(z) = z^{-2} + \frac{1}{20}g_2z^2 + \frac{1}{28}g_3z^4 + \mathcal{O}(z^6) \quad (15)$$

$$\wp'(z) = -2z^{-3} + \frac{1}{10}g_2z + \frac{1}{7}g_3z^3 + \mathcal{O}(z^5). \quad (16)$$

Now cube (15) and square (16)

$$\wp^3(z) = z^{-6} + \frac{3}{20}g_2z^{-2} + \frac{3}{28}g_3 + \mathcal{O}(z^2) \quad (17)$$

$$\wp'^2(z) = 4z^{-6} - \frac{2}{5}g_2z^{-2} - \frac{4}{7}g_3 + \mathcal{O}(z^2). \quad (18)$$

Taking (18) - 4 × (17) cancels out the  $z^{-6}$  term, giving

$$\begin{aligned} \wp'^2(z) - 4\wp^3(z) &= \left(-\frac{2}{5} - \frac{3}{5}\right)g_2z^{-2} + \left(-\frac{4}{7} - \frac{3}{7}\right)g_3 + \mathcal{O}(z^2) \\ &= -g_2z^{-2} - g_3 + \mathcal{O}(z^2) \end{aligned} \quad (19)$$

$$\wp'^2(z) - 4\wp^3(z) + g_2z^{-2} + g_3 = \mathcal{O}(z^2). \quad (20)$$

But, from (5)

$$\wp(z) = z^{-2} + \frac{1}{2!}f''(0)z^2 + \frac{1}{4}f^{(4)}(0)z^4 + \dots, \quad (21)$$

so  $\wp(z) = z^{-2} + \mathcal{O}(z^2)$  and (20) can be written

$$\wp'^2(z) - 4\wp^3(z) + g_2\wp(z) + g_3 = \mathcal{O}(z^2). \quad (22)$$

The Weierstraß elliptic function is analytic at the origin and therefore at all points congruent to the origin. There are no other places where a singularity can occur, so this function is an ELLIPTIC FUNCTION with no SINGULARITIES. By LIOUVILLE'S ELLIPTIC FUNCTION THEOREM, it is therefore a constant. But as  $z \rightarrow 0$ ,  $\mathcal{O}(z^2) \rightarrow 0$ , so

$$\wp'^2(z) = 4\wp^3(z) - g_2\wp(z) - g_3. \quad (23)$$

The solution to the differential equation

$$y'^2 = 4y^3 - g_2y - g_3 \quad (24)$$

is therefore given by  $y = \wp(z + \alpha)$ , providing that numbers  $\omega_1$  and  $\omega_2$  exist which satisfy the equations defining the INVARIANTS. Writing the differential equation in terms of its roots  $e_1$ ,  $e_2$ , and  $e_3$ ,

$$y'^2 = 4y^3 - g_2y - g_3 = 4(y - e_1)(y - e_2)(y - e_3) \quad (25)$$

$$2\ln(y') = \ln 4 + \sum_{r=1}^3 \ln(y - e_r) \quad (26)$$

$$\frac{2y''}{y'} = y' \sum_{r=1}^3 (y - e_r)^{-1} \quad (27)$$

$$\frac{2y''}{y'^2} = \sum_{r=1}^3 (y - e_r)^{-1} \quad (28)$$

$$2 \frac{y'^2 y''' - y''(2y'y'')}{y'^4} = -y' \sum_{r=1}^3 (y - e_r)^{-2} \quad (29)$$

$$\frac{2y'''}{y'^3} - \frac{4y''^2}{y'^4} = - \sum_{r=1}^3 (y - e_r)^{-2}. \quad (30)$$

Now take (30)/4 + [(30)/4]^2,

$$\begin{aligned} \left[ \frac{y'''}{2y'^3} - \frac{y''^2}{y'^4} \right] + \left[ \frac{y''^2}{4y'^4} \right] \\ = -\frac{1}{4} \sum_{r=1}^3 (y - e_r)^{-2} + \frac{1}{16} \left[ \sum_{r=1}^3 (y - e_r)^{-1} \right]^2 \end{aligned} \quad (31)$$

$$\frac{3y''^2}{4y'^4} - \frac{y'''}{2y'^3} = \frac{3}{16} \sum_{r=1}^3 (y - e_r)^{-2} - \frac{3}{8} y \prod_{r=1}^3 (y - e_r)^{-1}. \quad (32)$$

The term on the right is half the SCHWARZIAN DERIVATIVE.

The DERIVATIVE of the Weierstraß elliptic function is given by

$$\begin{aligned} \wp'(z) &= \frac{d}{dz} \wp(z) = -2 \sum_{m,n} \frac{1}{(z - \Omega_{mn})^3} \\ &= -2z^{-3} - 2 \sum'_{m,n} (z - \Omega_{mn})^{-3}. \end{aligned} \quad (33)$$

This is an ODD FUNCTION which is itself an elliptic function with pole of order 3 at  $z = 0$ . The INTEGRAL is given by

$$z = \int_{\wp(z)}^{\infty} (4t^3 - g_2t - g_3)^{-1/2} dt. \quad (34)$$

A duplication formula is obtained as follows.

$$\begin{aligned} \wp(2z) &= \lim_{y \rightarrow z} \wp(y + z) = \frac{1}{4} \lim_{y \rightarrow z} \left[ \frac{\wp'(z) - \wp'(y)}{\wp(z) - \wp(y)} \right]^2 \\ &\quad - \wp(z) - \lim_{y \rightarrow z} \wp(y) \\ &= \frac{1}{4} \lim_{h \rightarrow 0} \left[ \frac{\wp(z) - \wp'(z+h)}{\wp(z) - \wp(z+h)} \right]^2 - 2\wp(z) \\ &= \frac{1}{4} \left\{ \left[ \lim_{h \rightarrow 0} \frac{\wp'(z) - \wp'(z+h)}{h} \right] \left[ \lim_{h \rightarrow 0} \frac{h}{\wp(z) - \wp(z+h)} \right] \right\}^2 \\ &\quad - 2\wp(z) \\ &= \frac{1}{4} \left[ \frac{\wp''(z)}{\wp'(z)} \right]^2 - 2\wp(z). \end{aligned} \quad (35)$$

A general addition theorem is obtained as follows. Given

$$\wp'(z) = A\wp(z) + B \quad (36)$$

$$\wp'(y) = A\wp(y) + B \quad (37)$$

with zero  $y$  and  $z$  where  $z \not\equiv \pm y \pmod{2\omega_1, 2\omega_2}$ , find the third zero  $\zeta$ . Consider  $\wp'(\zeta) - A\wp(\zeta) - B$ . This has a pole of order three at  $\zeta = 0$ , but the sum of zeros (= 0) equals the sum of poles for an ELLIPTIC FUNCTION, so  $z + y + \zeta = 0$  and  $\zeta = -z - y$ .

$$\wp'(-z - y) = A\wp(-z - y) + B \quad (38)$$

$$-\wp'(z+y) = A\wp(z+y) + B. \quad (39)$$

Combining (36), (37), and (39) gives

$$\begin{bmatrix} \wp(z) & \wp'(z) & 1 \\ \wp(y) & \wp'(y) & 1 \\ \wp(z+y) & -\wp'(z+y) & 1 \end{bmatrix} \begin{bmatrix} A \\ -1 \\ B \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}, \quad (40)$$

so

$$\begin{vmatrix} \wp(z) & \wp'(z) & 1 \\ \wp(y) & \wp'(y) & 1 \\ \wp(z+y) & -\wp'(z+y) & 1 \end{vmatrix} = 0. \quad (41)$$

Defining  $u+v+w=0$  where  $u \equiv z$  and  $v \equiv y$  gives the symmetric form

$$\begin{vmatrix} \wp(u) & \wp'(u) & 1 \\ \wp(v) & \wp'(v) & 1 \\ \wp(w) & \wp'(w) & 1 \end{vmatrix} = 0. \quad (42)$$

To get the expression explicitly, start again with

$$\wp'(\zeta) - A\wp(\zeta) - B = 0, \quad (43)$$

where  $\zeta = z, y, -z-y$ .

$$\wp'^2(\zeta) - [A\wp(\zeta) + B]^2 = 0. \quad (44)$$

But  $\wp^2(\zeta) = 4\wp^4(\zeta) - g_2\wp(\zeta) - g_3$ , so

$$4\wp^3(\zeta) - A^2\wp^2(\zeta) - (2AB + g_2)\wp(\zeta) - (B^2 + g_3) = 0. \quad (45)$$

The solutions  $\wp(\zeta) \equiv z$  are given by

$$4z^3 - A^2z^2 - (2AB + g_2)z - (B^2 + g_3) = 0. \quad (46)$$

But the sum of roots equals the COEFFICIENT of the squared term, so

$$\wp(z) + \wp(y) + \wp(z+y) = \frac{1}{4}A^2 \quad (47)$$

$$\wp'(z) - \wp'(y) = A[\wp(z) - \wp(y)] \quad (48)$$

$$A = \frac{\wp'(z) - \wp'(y)}{\wp(z) - \wp(y)} \quad (49)$$

$$\wp(z+y) = \frac{1}{4} \left[ \frac{\wp(z) - \wp'(y)}{\wp(z) - \wp(y)} \right]^2 - \wp(z) - \wp(y). \quad (50)$$

Half-period identities include

$$\begin{aligned} x \equiv \wp(\tfrac{1}{2}\omega_1) &= \wp(-h\omega_1 + \omega_1) = e_1 + \frac{(e_1 - e_2)(e_1 - e_3)}{\wp(-\tfrac{1}{2}\omega_1) - e_1} \\ &= e_1 + \frac{(e_1 - e_2)(e_1 - e_3)}{x - e_1}. \end{aligned} \quad (51)$$

Multiplying through,

$$x^2 - e_1x = e_1x - e_1^2 + (e_1 - e_2)(e_1 - e_3) \quad (52)$$

$$x^2 - 2e_1 + [e_1^2 - (e_1 - e_2)(e_1 - e_3)] = 0, \quad (53)$$

which gives

$$\begin{aligned} \wp(\tfrac{1}{2}\omega_1) &= \tfrac{1}{2} \left\{ 2e_1 \pm \sqrt{4e_1^2 - 4[e_1^2 - (e_1 - e_2)(e_1 - e_3)]} \right\} \\ &= e_1 \pm \sqrt{(e_1 - e_2)(e_1 - e_3)}. \end{aligned} \quad (54)$$

From Whittaker and Watson (1990, p. 445),

$$\wp'(\tfrac{1}{2}\omega_1) = -2\sqrt{(e_1 - e_2)(e_1 - e_3)} \times (\sqrt{e_1 - e_2} + \sqrt{e_1 - e_3}). \quad (55)$$

The function is HOMOGENEOUS,

$$\wp(\lambda z | \lambda\omega_1, \lambda\omega_2) = \lambda^{-2} \wp(z | \omega_1, \omega_2) \quad (56)$$

$$\wp(\lambda z; \lambda^{-4}g_2, \lambda^{-6}g_3) = \lambda^{-2} \wp(z; g_2, g_3). \quad (57)$$

To invert the function, find  $2\omega_1$  and  $2\omega_2$  of  $\wp(z | \omega_1, \omega_2)$  when given  $\wp(z; g_2, g_3)$ . Let  $e_1, e_2$ , and  $e_3$  be the roots such that  $(e_1 - e_2)/(e_1 - e_3)$  is not a REAL NUMBER  $> 1$  or  $< 0$ . Determine the PARAMETER  $\tau$  from

$$\frac{e_1 - e_2}{e_1 - e_3} = \frac{\vartheta_4^4(0|\tau)}{\vartheta_3^4(0|\tau)}. \quad (58)$$

Now pick

$$A \equiv \frac{\sqrt{e_1 - e_2}}{\vartheta_4^2(0|\tau)}. \quad (59)$$

As long as  $g_2^3 \neq 27g_3$ , the periods are then

$$2\omega_1 = \pi A \quad (60)$$

$$2\omega_2 = \frac{\pi\tau}{A}. \quad (61)$$

Weierstraß elliptic functions can be expressed in terms of JACOBI ELLIPTIC FUNCTIONS by

$$\begin{aligned} \wp(u; g_2, g_3) &= e_3 + (e_1 - e_3) \\ &\times \text{ns}^2 \left( u\sqrt{e_1 - e_3}, \sqrt{\frac{e_2 - e_3}{e_1 - e_3}} \right), \end{aligned} \quad (62)$$

where

$$\wp(\omega_1) = e_1 \quad (63)$$

$$\wp(\omega_2) = e_2 \quad (64)$$

$$\wp(\omega_3) = -\wp(-\omega_1 - \omega_2) = e_3, \quad (65)$$

and the INVARIANTS are

$$g_2 \equiv 60\Sigma' \Omega_{mn}^{-4} \quad (66)$$

$$g_3 \equiv 140\Sigma' \Omega_{mn}^{-6}. \quad (67)$$

Here,  $\Omega_{mn} \equiv 2m\omega_1 - 2n\omega_2$ .

An addition formula for the Weierstraß elliptic function can be derived as follows.

$$\wp(z + \omega_1) + \wp(z) + \wp(\omega_1) = \frac{1}{4} \left[ \frac{\wp'(z) - \wp'(\omega_1)}{\wp(z) - \wp(\omega_1)} \right]^2 = \frac{1}{4} \frac{\wp'^2(z)}{[\wp(z) - e_1]^2}. \quad (68)$$

Use

$$\wp'(z) = 4 \prod_{r=1}^3 [\wp(z) - e_r], \quad (69)$$

so

$$\begin{aligned} \wp(z + \omega_1) &= -\wp(z) - e_1 + \frac{1}{4} \frac{4 \prod_{r=1}^3 [\wp(z) - e_r]}{[\wp(z) - e_1]^2} \\ &= -\wp(z) - e_1 + \frac{[\wp(z) - e_2][\wp(z) - e_3]}{\wp(z) - e_1}. \end{aligned} \quad (70)$$

$$\text{Use } \sum_{r=1}^3 e_r = 0,$$

$$\begin{aligned} \wp(z + \omega_1) &= e_1 + \frac{[-2e_1 - \wp(z)][\wp(z) - e_1]}{\wp(z) - e_1} \\ &\quad + \frac{\wp^2(z) - \wp(z)(e_2 + e_3) + e_2e_3}{\wp(z) - e_1} \\ &= e_1 + \frac{-\wp(z)(e_1 + e_2 + e_3) + e_2e_3 + 2e_1^2}{\wp(z) - e_1}. \end{aligned} \quad (71)$$

$$\text{But } \sum_{r=1}^3 e_r = 0 \text{ and}$$

$$2e_1^2 + e_2e_3 = e_1^2 - e_1(e_2 + e_3) + e_2e_3 = (e_1 - e_2)(e_1 - e_3), \quad (72)$$

so

$$\wp(z + \omega_1) = e_1 + \frac{(e_1 - e_2)(e_1 - e_3)}{\wp(z) - e_1}. \quad (73)$$

The periods of the Weierstraß elliptic function are given as follows. When  $g_2$  and  $g_3$  are REAL and  $g_2^3 - 27g_3^2 > 0$ , then  $e_1, e_2$ , and  $e_3$  are REAL and defined such that  $e_1 > e_2 > e_3$ .

$$\omega_1 = \int_{e_1}^{\infty} (4t^3 - g_2t - g_3)^{-1/2} dt \quad (74)$$

$$\omega_3 = -i \int_{-\infty}^{e_3} (g_3 + g_2t - 4t^3)^{-1/2} dt \quad (75)$$

$$\omega_2 = -\omega_1 - \omega_3. \quad (76)$$

The roots of the Weierstraß elliptic function satisfy

$$e_1 = \wp(\omega_1) \quad (77)$$

$$e_2 = \wp(\omega_2) \quad (78)$$

$$e_3 = \wp(\omega_3), \quad (79)$$

where  $\omega_3 \equiv -\omega_1 - \omega_2$ . The  $e_i$ s are ROOTS of  $4t^3 - g_2t - g_3$  and are unequal so that  $e_1 \neq e_2 \neq e_3$ . They can be found from the relationships

$$e_1 + e_2 + e_3 = -a_2 = 0 \quad (80)$$

$$e_2e_3 + e_3e_1 + e_1e_2 = a_1 = -\frac{1}{4}g_2 \quad (81)$$

$$e_1e_2e_3 = -a_0 = \frac{1}{4}g_3. \quad (82)$$

### Weierstraß-Erdman Corner Condition

In the CALCULUS OF VARIATIONS, the condition

$$f_{y'}(x, y, y'(x-)) = f_{y'}(x, y, y'(x+))$$

must hold at a corner  $(x, y)$  of a minimizing arc  $E_{12}$ .

### Weierstraß Extreme Value Theorem

see EXTREME VALUE THEOREM

### Weierstraß Form

A general form into which an ELLIPTIC CURVE over any FIELD  $K$  can be transformed is called the Weierstraß form, and is given by

$$y^2 + ay = x^3 + bx^2 + cxy + dx + e,$$

where  $a, b, c, d$ , and  $e$  are elements of  $K$ .

### Weierstraß Function

A CONTINUOUS FUNCTION which is nowhere DIFFERENTIABLE. It is given by

$$f(x) = \sum_{n=1}^{\infty} b^n \cos(a^n \pi x)$$

where  $n$  is an ODD INTEGER,  $b \in (0, 1)$ , and  $ab > 1 + 3\pi/2$ . The above plot is for  $a = 10$  and  $b = 1/2$ .

#### Weierstraß's Gap Theorem

Given a succession of nonsingular points which are on a nonhyperelliptic curve of GENUS  $p$ , but are not a group of the canonical series, the number of groups of the first  $k$  which cannot constitute the group of simple POLES of a RATIONAL FUNCTION is  $p$ . If points next to each other are taken, then the theorem becomes: Given a nonsingular point of a nonhyperelliptic curve of GENUS  $p$ , then the orders which it cannot possess as the single pole of a RATIONAL FUNCTION are  $p$  in number.

#### Weierstraß Intermediate Value Theorem

If a continuous function defined on an interval is sometimes POSITIVE and sometimes NEGATIVE, it must be 0 at some point.

#### Weierstraß M-Test

Let  $\sum_{k=1}^{\infty} u_n(x)$  be a SERIES of functions all defined for a set  $E$  of values of  $x$ . If there is a CONVERGENT series of constants

$$\sum_{n=1}^{\infty} M_n,$$

such that

$$|u_n(x)| \leq M_n$$

for all  $x \in E$ , then the series exhibits ABSOLUTE CONVERGENCE for each  $x \in E$  as well as UNIFORM CONVERGENCE in  $E$ .

#### Weierstraß Sigma Function

The QUASIPERIODIC FUNCTION defined by

$$\frac{d}{dz} \ln \sigma(z) = \zeta(z), \quad (1)$$

where  $\zeta(z)$  is the WEIERSTRASS ZETA FUNCTION and

$$\lim_{z \rightarrow 0} \frac{\sigma(z)}{z} = 1. \quad (2)$$

Then

$$\sigma(z) = z \prod_{mn}' \left[ \left( 1 - \frac{z}{\Omega_{mn}} \right) \exp \left( \frac{z}{\Omega_{mn}} + \frac{z^2}{2\Omega_{mn}^2} \right) \right] \quad (3)$$

$$\sigma(z + 2\omega_1) = -e^{2\eta_1(z+\omega_1)} \sigma(z) \quad (4)$$

$$\sigma(z + 2\omega_2) = -e^{2\eta_2(z+\omega_2)} \sigma(z) \quad (5)$$

$$\sigma_r(z) = \frac{e^{-\eta_r z} \sigma(z + \omega_r)}{\sigma(\omega_r)} \quad (6)$$

for  $r = 1, 2, 3$ .

$$\sigma(z|\omega_1, \omega_2) = \frac{2\omega_1}{\pi\vartheta_1'} \exp\left(-\frac{\nu^2 \vartheta_1'''}{6\vartheta_1'}\right) \vartheta_1\left(\nu \left|\frac{\omega_2}{\omega_1}\right.\right), \quad (7)$$

where  $\nu \equiv \pi z/(2\omega_1)$ , and

$$\eta_1 = -\frac{\pi^2 \vartheta_1'''}{12\omega_1 \vartheta_1'} \quad (8)$$

$$\eta_2 = -\frac{\pi^2 \omega_2 \vartheta_1'''}{12\omega_1^2 \vartheta_1'} - \frac{\pi i}{2\omega_1}. \quad (9)$$

### References

Abramowitz, M. and Stegun, C. A. (Eds.). "Weierstrass Elliptic and Related Functions." Ch. 18 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, pp. 627–671, 1972.

### Weierstraß's Theorem

The only hypercomplex number systems with commutative multiplication and addition are the algebra with one unit such that  $e = e^2$  and the GAUSSIAN INTEGERS. see also GAUSSIAN INTEGER, PEIRCE'S THEOREM

### Weierstraß Zeta Function

The QUASIPERIODIC FUNCTION defined by

$$\frac{d\zeta(z)}{dz} = -\wp(z) \quad (1)$$

with

$$\lim_{z \rightarrow 0} [\zeta(z) - z^{-1}] = 0. \quad (2)$$

Then

$$\begin{aligned} \zeta(z) - z^{-1} &= -\int_0^z [\wp(z) - z^{-2}] dz \\ &= -\Sigma' \int_0^z [(z - \Omega_{mn})^{-2} - \Omega_{mn}^{-2}] dz \end{aligned} \quad (3)$$

$$\zeta(z) = z^{-1} + \sum_{m,n=-\infty}^{\infty} [(z - \Omega_{mn})^{-1} + \Omega_{mn}^{-1} + z\Omega_{mn}^{-2}] \quad (4)$$

so  $\zeta(z)$  is an ODD FUNCTION. Integrating  $\wp(z + 2\omega_1) = \wp(z)$  gives

$$\zeta(z + 2\omega_1) = \zeta(z) + 2\eta_1. \quad (5)$$

Letting  $z = -\omega_1$  gives  $\zeta(-\omega_1) + 2\eta_1 = -\zeta(\omega_1) + 2\eta_1$ , so  $\eta_1 = \zeta(\omega_1)$ . Similarly,  $\eta_2 = \zeta(\omega_2)$ . From Whittaker and Watson (1990),

$$\eta_1 \omega_2 - \eta_2 \omega_1 = \frac{1}{2} \pi i. \quad (6)$$

If  $x + y + z = 0$ , then

$$[\zeta(x) + \zeta(y) + \zeta(z)]^2 + \zeta'(x) + \zeta'(y) + \zeta'(z) = 0. \quad (7)$$

Also,

$$2 \frac{\begin{vmatrix} 1 & \wp(x) & \wp^2(x) \\ 1 & \wp(y) & \wp^2(y) \\ 1 & \wp(z) & \wp^2(z) \end{vmatrix}}{\begin{vmatrix} 1 & \wp(x) & \wp'(x) \\ 1 & \wp(y) & \wp'(y) \\ 1 & \wp(z) & \wp'(z) \end{vmatrix}} = \zeta(x+y+z) - \zeta(x) - \zeta(y) - \zeta(z) \quad (8)$$

(Whittaker and Watson 1990, p. 446).

### Weighings

$n$  weighings are SUFFICIENT to find a bad COIN among  $(3^n - 1)/2$  COINS. vos Savant (1993) gives an algorithm for finding a bad ball among 12 balls in three weighings (which, in addition, determines if the bad ball is heavier or lighter than the other 11).

Bachet's weights problem asks for the *minimum number* of weights (which can be placed in *either* pan of a two-arm balance) required to weigh any integral number of pounds from 1 to 40. The solution is 1, 3, 9, and 27:  $1, 2 = -1 + 3, 3, 4 = 1 + 3, 5 = -1 - 3 + 9, 6 = -3 + 9, 7 = 1 - 3 + 9, 8 = -1 + 9, 9, 10 = 1 + 9, 11 = -1 + 3 + 9, 12 = 3 + 9, 13 = 1 + 3 + 9, 14 = -1 - 3 - 9 + 27, 15 = -3 - 9 + 27, 16 = 1 - 3 - 9 + 27, 17 = -1 - 9 + 27$ , and so on.

**Weight**

The word weight has many uses in mathematics. It can refer to a function  $w(x)$  (also called a WEIGHTING FUNCTION or WEIGHT FUNCTION) used to normalize ORTHONORMAL FUNCTIONS. It can also be used to indicate one of a set of a multiplicative constants placed in front of terms in a MOVING AVERAGE, NEWTON-COTES FORMULAS, edge or vertex of a GRAPH or TREE, etc.

see also WEIGHTED TREE, WEIGHTING FUNCTION

**Weight Function**

see WEIGHTING FUNCTION

**Weighted Tree**

A TREE in which each branch is given a numerical WEIGHT (i.e., a labelled TREE).

see also LABELLED GRAPH, TAYLOR'S CONDITION, TREE

**Weighting Function**

A function  $w(x)$  used to normalize ORTHONORMAL FUNCTIONS

$$\int [f_n(x)]^2 w(x) dx = N_n.$$

see also WEIGHT

**Weingarten Equations**

The Weingarten equations express the derivatives of the NORMAL using derivatives of the position vector. Let  $\mathbf{x} : U \rightarrow \mathbb{R}^3$  a REGULAR PATCH, then the SHAPE OPERATOR  $S$  of  $\mathbf{x}$  is given in terms of the basis  $\{\mathbf{x}_u, \mathbf{x}_v\}$  by

$$-S(\mathbf{x}_u) = \mathbf{N}_u = \frac{fF - eG}{EG - F^2} \mathbf{x}_u + \frac{eF - fE}{EG - F^2} \mathbf{x}_v \quad (1)$$

$$-S(\mathbf{x}_v) = \mathbf{N}_v = \frac{gF - fG}{EG - F^2} \mathbf{x}_u + \frac{fF - gE}{EG - F^2} \mathbf{x}_v, \quad (2)$$

where  $\mathbf{N}$  is the NORMAL VECTOR,  $E, F$ , and  $G$  the coefficients of the first FUNDAMENTAL FORM

$$ds^2 = E du^2 + 2F du dv + G dv^2, \quad (3)$$

and  $e, f$ , and  $g$  the coefficients of the second FUNDAMENTAL FORM given by

$$e = -\mathbf{N}_u \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uu} \quad (4)$$

$$\begin{aligned} f &= -\mathbf{N}_v \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uv} \\ &= \mathbf{N}_{vu} \cdot \mathbf{x}_u = -\mathbf{N}_u \cdot \mathbf{x}_v \end{aligned} \quad (5)$$

$$g = -\mathbf{N}_v \cdot \mathbf{x}_v = \mathbf{N} \cdot \mathbf{x}_{vv}. \quad (6)$$

**Weingarten Map**

see SHAPE OPERATOR

**Weird Number**

A number which is ABUNDANT without being SEMIPERFECT. (A SEMIPERFECT NUMBER is the sum of any set of its own DIVISORS.) The first few weird numbers are 70, 836, 4030, 5830, 7192, 7912, 9272, 10430, ... (Sloane's A006037). No ODD weird numbers are known, but an infinite number of weird numbers are known to exist. The SEQUENCE of weird numbers has POSITIVE SCHNIRELMANN DENSITY.

see also ABUNDANT NUMBER, SCHNIRELMANN DENSITY, SEMIPERFECT NUMBER

**Welch Apodization Function**

The APODIZATION FUNCTION

$$A(x) = 1 - \frac{x^2}{a^2}.$$

Its FULL WIDTH AT HALF MAXIMUM is  $\sqrt{2}a$ . Its INSTRUMENT FUNCTION is

$$\begin{aligned} I(k) &= a^2 \sqrt{2\pi} \frac{J_{3/2}(2\pi ka)}{(2\pi ka)^{3/2}} \\ &= a \frac{\sin(2\pi ka) - 2\pi ka \cos(2\pi ka)}{2a^3 k^3 \pi^3}, \end{aligned}$$

where  $J_\nu(z)$  is a BESSEL FUNCTION OF THE FIRST KIND. It has a width of 1.59044, a maximum of  $\frac{4}{3}$ , maximum NEGATIVE sidelobe of  $-0.0861713$  times the peak, and maximum POSITIVE sidelobe of 0.356044 times the peak.

see also APODIZATION FUNCTION, INSTRUMENT FUNCTION

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, p. 547, 1992.

## Well-Defined

An expression is called well-defined (or UNAMBIGUOUS) if its definition assigns it a unique interpretation or value. Otherwise, the expression is said to not be well defined or to be AMBIGUOUS.

For example, the expression  $abc$  (the PRODUCT) is well-defined if  $a$ ,  $b$ , and  $c$  are integers. Because integers are ASSOCIATIVE,  $abc$  has the same value whether it is interpreted to mean  $(ab)c$  or  $a(bc)$ . However, if  $a$ ,  $b$ , and  $c$  are MATRICES or CAYLEY NUMBERS, then the expression  $abc$  is *not* well-defined, since MATRICES and CAYLEY NUMBER are not, in general, ASSOCIATIVE, so that the two interpretations  $(ab)c$  and  $a(bc)$  can be different.

Sometimes, ambiguities are implicitly resolved by notational convention. For example, the conventional interpretation of  $a \wedge b \wedge c = a^{b^c}$  is  $a^{(b^c)}$ , never  $(a^b)^c$ , so that the expression  $a \wedge b \wedge c$  is well-defined even though exponentiation is nonassociative.

## Well-Ordered Set

A SET having the property that every nonempty SUBSET has a least member.

see also AXIOM OF CHOICE, HILBERT'S PROBLEMS, SUBSET, WELL-ORDERING PRINCIPLE

## Well-Ordering Principle

Every nonempty set of POSITIVE integers contains a smallest member.

see also WELL-ORDERED SET

## Weyl Tensor

The TENSOR

$$C^{ij}{}_{kl} = R^i{}_{jkl} - 2\delta^{[i}{}_k R^{j]}{}_{l]} + \frac{1}{3}\delta^{[i}{}_k \delta^{j]}{}_{l]} R,$$

where  $R^i{}_{jkl}$  is the RIEMANN TENSOR and  $R$  is the CURVATURE SCALAR. The Weyl tensor is defined so that every CONTRACTION between indices gives 0. In particular,  $C^\lambda{}_{\mu\lambda\kappa} = 0$ . The number of independent components for a Weyl tensor in  $N$ -D is given by

$$C_N = \frac{1}{12}N(N+1)(N+2)(N-3).$$

see also CURVATURE SCALAR, RIEMANN TENSOR

## References

## Wheat and Chessboard Problem

Let one grain of wheat be placed on the first square of a CHESSBOARD, two on the second, three on the third, etc. How many grains total are placed on an  $8 \times 8$  CHESSBOARD? Since this is a GEOMETRIC SERIES, the answer for  $n$  squares is

$$\sum_{i=0}^{n-1} 2^i = 2^n - 1.$$

Plugging in  $n = 8 \times 8 = 64$  then gives  $2^{64} - 1 = 18446744073709551615$ .

### Whitehead's Theorem

MAPS between CW-COMPLEXES that induce ISOMORPHISMS on all HOMOTOPY GROUPS are actually HOMOTOPY equivalences.

see also CW-COMPLEX, HOMOTOPY GROUP, ISOMORPHISM

### Whitney-Graustein Theorem

A 1937 theorem which classified planar regular closed curves up to regular HOMOTOPY by their WINDING NUMBERS. In his thesis, S. Smale generalized this result to regular closed curves on an  $n$ -MANIFOLD.

### Whitney-Mikhlin Extension Constants

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let  $B_n(r)$  be the  $n$ -D closed BALL of RADIUS  $r > 1$  centered at the ORIGIN. A function which is defined on  $B(r)$  is called an extension to  $B(r)$  of a function  $f$  defined on  $B(1)$  if

$$F(x) = f(x) \forall x \in B(1). \quad (1)$$

Given 2 BANACH SPACES of functions defined on  $B(1)$  and  $B(r)$ , find the extension operator from one to the other of minimal norm. Mikhlin (1986) found the best constants  $\chi$  such that this condition, corresponding to the Sobolev  $W(1, 2)$  integral norm, is satisfied,

$$\sqrt{\int_{B(1)} \left[ [f(x)]^2 + \sum_{j=1}^n \left( \frac{\partial f}{\partial x_j} \right)^2 \right] dx} \leq \chi \sqrt{\int_{B(r)} \left[ [F(x)]^2 + \sum_{j=1}^n \left( \frac{\partial F}{\partial x_j} \right)^2 \right] dx}. \quad (2)$$

$\chi(1, r) = 1$ . Let

$$\nu = \frac{1}{2}(n - 2), \quad (3)$$

then for  $n > 2$ ,

$$\chi(n, r) = \sqrt{1 + \frac{I_\nu(1)}{I_{\nu+1}(1)} \frac{I_\nu(r)K_{\nu+1}(1) + K_\nu(r)I_{\nu+1}(1)}{I_\nu(r)K_\nu(1) - K_\nu(r)I_\nu(1)}}, \quad (4)$$

where  $I_\nu(z)$  is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND and  $K_\nu(z)$  is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND. For  $n = 2$ ,

$$\chi(2, r) = \max \left\{ \sqrt{1 + \frac{I_\nu(1)}{I_{\nu+1}(1)} \frac{I_\nu(r)K_{\nu+1}(1) + K_\nu(r)I_{\nu+1}(1)}{I_\nu(r)K_\nu(1) - K_\nu(r)I_\nu(1)}}, \sqrt{1 + \frac{I_1(1)}{I_1(1) + I_2(1)} \left[ 1 + \frac{I_1(r)K_0(1) + K_1(r)I_0(1)}{I_1(r)K_1(1) - K_1(r)I_1(1)} \right]} \right\}. \quad (5)$$

For  $r \rightarrow \infty$ ,

$$\chi(n, \infty) = \sqrt{1 + \frac{I_\nu(1)}{I_{\nu+1}(1)} \frac{K_\nu(1)}{K_{\nu+1}(1)}}, \quad (6)$$

which is bounded by

$$n - 1 < \chi(n, \infty) < \sqrt{(n - 1)^2 + 4}. \quad (7)$$

For ODD  $n$ , the RECURRENCE RELATIONS

$$a_{k+1} = a_{k-1} - (2k - 1)a_k \quad (8)$$

$$b_{k+1} = b_{k-1} + (2k - 1)b_k \quad (9)$$

with

$$a_0 = e + e^{-1} \quad (10)$$

$$a_1 = e - e^{-1} \quad (11)$$

$$b_0 = e^{-1} \quad (12)$$

$$b_1 = e^{-1} \quad (13)$$

where  $e$  is the constant 2.71828..., give

$$\chi(2k + 1, \infty) = \sqrt{1 + \frac{a_k}{a_{k+1}} \frac{b_{k+1}}{b_k}}. \quad (14)$$

The first few are

$$\chi(3, \infty) = e \quad (15)$$

$$\chi(5, \infty) = \sqrt{\frac{e^2}{e^2 - 7}} \quad (16)$$

$$\chi(7, \infty) = \sqrt{\frac{2}{7}} \sqrt{\frac{e^2}{37 - 5e^2}} \quad (17)$$

$$\chi(9, \infty) = \frac{1}{\sqrt{37}} \sqrt{\frac{e^2}{18e^2 - 133}} \quad (18)$$

$$\chi(11, \infty) = \frac{1}{\sqrt{133}} \sqrt{\frac{e^2}{2431 - 329e^2}} \quad (19)$$

$$\chi(13, \infty) = \sqrt{\frac{2}{2431}} \sqrt{\frac{e^2}{3655e^2 - 27007}}. \quad (20)$$

Similar formulas can be given for even  $n$  in terms of  $I_0(1)$ ,  $I_1(1)$ ,  $K_0(1)$ ,  $K_1(1)$ .

**Whitney Singularity**

see PINCH POINT

**Whitney Sum**

An operation that takes two VECTOR BUNDLES over a fixed SPACE and produces a new VECTOR BUNDLE over the same SPACE. If  $E_1$  and  $E_2$  are VECTOR BUNDLES over  $B$ , then the Whitney sum  $E_1 \oplus E_2$  is the VECTOR BUNDLE over  $B$  such that each FIBER over  $B$  is naturally the direct sum of the  $E_1$  and  $E_2$  FIBERS over  $B$ .

The Whitney sum is therefore the FIBER for FIBER direct sum of the two BUNDLES  $E_1$  and  $E_2$ . An easy formal definition of the Whitney sum is that  $E_1 \oplus E_2$  is the pull-back BUNDLE of the diagonal map from  $B$  to  $B \times B$ , where the BUNDLE over  $B \times B$  is  $E_1 \times E_2$ .

see also BUNDLE, FIBER, VECTOR BUNDLE

**Whitney Umbrella**

A surface which can be interpreted as a self-intersecting RECTANGLE in 3-D. It is given by the parametric equations

$$x = uv \quad (1)$$

$$y = u \quad (2)$$

$$z = v^2 \quad (3)$$

for  $u, v \in [-1, 1]$ . The center of the "plus" shape which is the end of the line of self-intersection is a PINCH POINT. The coefficients of the first FUNDAMENTAL FORM are

$$E = 0 \quad (4)$$

$$F = \frac{2v}{\sqrt{u^2 + 4v^2 + 4v^4}} \quad (5)$$

$$G = -\frac{2u}{\sqrt{u^2 + 4v^2 + 4v^4}}, \quad (6)$$

and the coefficients of the second FUNDAMENTAL FORM are

$$e = 1 + v^2 \quad (7)$$

$$f = uv \quad (8)$$

$$g = u^2 + 4v^2, \quad (9)$$

giving GAUSSIAN CURVATURE and MEAN CURVATURE

$$K = -\frac{4v^2}{(u^2 + 4v^2 + 4v^4)^2} \quad (10)$$

$$H = -\frac{u(1 + 3v^2)}{(u^2 + 4v^2 + 4v^4)^{3/2}}. \quad (11)$$

**Whittaker Differential Equation**

$$\frac{d^2u}{dz^2} + \frac{du}{dz} + \left( \frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2} \right) u = 0. \quad (1)$$

Let  $u \equiv e^{-z/2} W_{k,m}(z)$ , where  $W_{k,m}(z)$  denotes a WHITTAKER FUNCTION. Then (1) becomes

$$\begin{aligned} \frac{d}{dz} \left( -\frac{1}{2} e^{-z/2} W + e^{-z/2} W' \right) + \left( -\frac{1}{2} e^{-z/2} W + e^{-z/2} W' \right) \\ + \left( \frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2} \right) e^{-z/2} W = 0. \end{aligned} \quad (2)$$

Rearranging,

$$\begin{aligned} \left( \frac{1}{4} e^{-z/2} W - \frac{1}{2} e^{-z/2} W' - \frac{1}{2} e^{-z/2} W' + e^{-z/2} W'' \right) p \\ + \left( -\frac{1}{2} e^{-z/2} W + e^{-z/2} W' \right) + \left( \frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2} \right) e^{-z/2} W \\ = 0 \end{aligned} \quad (3)$$

$$-\frac{1}{4} e^{-z/2} W + e^{-z/2} W'' + \left( \frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2} \right) e^{-z/2} W = 0, \quad (4)$$

so

$$W'' + \left( -\frac{1}{4} + \frac{k}{z} + \frac{\frac{1}{4} - m^2}{z^2} \right) W = 0, \quad (5)$$

where  $W' \equiv dW/dz$ . The solutions are known as WHITTAKER FUNCTIONS.

**References**

**Whittaker Function**

Solutions to the WHITTAKER DIFFERENTIAL EQUATION. The linearly independent solutions are

$$M_{k,m}(z) \equiv z^{1/2+m} e^{-z/2} \times \left( 1 + \frac{\frac{1}{2} + m - k}{1!(2m+1)} + \frac{(\frac{1}{2} + m - k)(\frac{3}{2} + m - k)}{2!(2m+1)(2m+2)} z^2 + \dots \right), \quad (1)$$

and  $M_{k,-m}(z)$ , where  $M_{k,m}(z)$  is a CONFLUENT HYPERGEOMETRIC FUNCTION. In terms of CONFLUENT HYPERGEOMETRIC FUNCTIONS, the Whittaker functions are

$$M_{k,m}(z) = e^{-z/2} z^{m+1/2} {}_1F_1\left(\frac{1}{2} + m - k, 1 + 2m; z\right) \quad (2)$$

$$W_{k,m}(z) = e^{-z/2} z^{m+1/2} U\left(\frac{1}{2} + m - k, 1 + 2m; z\right) \quad (3)$$

(see Whittaker and Watson 1990, pp. 339–351). However, the CONFLUENT HYPERGEOMETRIC FUNCTION disappears when  $2m$  is an INTEGER, so Whittaker functions are often defined instead. The Whittaker functions are related to the PARABOLIC CYLINDER FUNCTIONS. When  $|\arg z| < 3\pi/2$  and  $2m$  is not an INTEGER,

$$W_{k,m}(z) = \frac{\Gamma(-2m)}{\Gamma(\frac{1}{2} - m - k)} M_{k,m}(z) + \frac{\Gamma(2m)}{\Gamma(\frac{1}{2} + m - k)} M_{k,-m}(z). \quad (4)$$

When  $|\arg(-z)| < 3\pi/2$  and  $2m$  is not an INTEGER,

$$W_{-k,m}(-z) = \frac{\Gamma(-2m)}{\Gamma(\frac{1}{2} - m - k)} M_{-k,m}(-z) + \frac{\Gamma(2m)}{\Gamma(\frac{1}{2} + m + k)} M_{-k,-m}(-z). \quad (5)$$

Whittaker functions satisfy the RECURRENCE RELATIONS

$$W_{k,m}(z) = z^{1/2} W_{k-1/2,m-1/2}(z) + \left(\frac{1}{2} - k + m\right) W_{k-1,m}(z) \quad (6)$$

$$W_{k,m}(z) = z^{1/2} W_{k-1/2,m+1/2}(z) + \left(\frac{1}{2} - k - m\right) W_{k-1,m}(z) \quad (7)$$

$$z W'_{k,m}(z) = \left(k - \frac{1}{2}\right) W_{k,m}(z) - \left[m^2 - \left(k - \frac{1}{2}\right)^2\right] W_{k-1,m}(z). \quad (8)$$

**Whole Number**

One of the numbers 1, 2, 3, ... (Sloane's A000027), also called the COUNTING NUMBERS or NATURAL NUMBERS. 0 is sometimes included in the list of "whole" numbers (Bourbaki 1968, Halmos 1974), but there seems to be no general agreement. Some authors also interpret "whole number" to mean "a number having FRACTIONAL PART of zero," making the whole numbers equivalent to the integers.

Due to lack of standard terminology, the following terms are recommended in preference to "COUNTING NUMBER," "NATURAL NUMBER," and "whole number."

Set	Name	Symbol
..., -2, -1, 0, 1, 2, ...	integers	$\mathbb{Z}$
1, 2, 3, 4, ...	positive integers	$\mathbb{Z}^+$
0, 1, 2, 3, 4, ...	nonnegative integers	$\mathbb{Z}^*$
-1, -2, -3, -4, ...	negative integers	$\mathbb{Z}^-$

see also COUNTING NUMBER, FRACTIONAL PART, INTEGER,  $\mathbb{N}$ , NATURAL NUMBER,  $\mathbb{Z}$ ,  $\mathbb{Z}^+$ ,  $\mathbb{Z}^*$ ,  $\mathbb{Z}^-$

**Wiedersehen Manifold**

The only Wiedersehen manifolds are the standard round spheres, as was established by proof of the BLASCHKE CONJECTURE.

see also BLASCHKE CONJECTURE

**Wieferich Prime**

A Wieferich prime is a PRIME  $p$  which is a solution to the CONGRUENCE equation

$$2^{p-1} \equiv 1 \pmod{p^2}.$$

Note the similarity of this expression to the special case of FERMAT'S LITTLE THEOREM

$$2^{p-1} \equiv 1 \pmod{p},$$

which holds for *all* ODD PRIMES. However, the only Wieferich primes less than  $4 \times 10^{12}$  are  $p = 1093$  and  $3511$  (Lehmer 1981, Crandall 1986, Crandall *et al.* 1997). Interestingly, one less than these numbers have suggestive periodic BINARY representations

$$\begin{aligned} 1092 &= 10001000100_2 \\ 3510 &= 110110110110_2. \end{aligned}$$

A PRIME factor  $p$  of a MERSENNE NUMBER  $M_q = 2^q - 1$  is a Wieferich prime IFF  $p^2 | 2^q - 1$ . Therefore, MERSENNE PRIMES are *not* Wieferich primes.

If the first case of FERMAT'S LAST THEOREM is false for exponent  $p$ , then  $p$  must be a Wieferich prime (Wieferich 1909). If  $p | 2^n \pm 1$  with  $p$  and  $n$  RELATIVELY PRIME, then  $p$  is a Wieferich prime IFF  $p^2$  also divides  $2^n \pm 1$ . The CONJECTURE that there are no three POWERFUL NUMBERS implies that there are infinitely many Wieferich primes (Granville 1986, Vardi 1991). In addition, the ABC CONJECTURE implies that there are at least  $C \ln x$  Wieferich primes  $\leq x$  for some constant  $C$  (Silverman 1988, Vardi 1991).

#### Wielandt's Theorem

Let the  $n \times n$  MATRIX  $A$  satisfy the conditions of the PERRON-FROBENIUS THEOREM and the  $n \times n$  MATRIX  $C = c_{ij}$  satisfy

$$|c_{ij}| \leq a_{ij}$$

for  $i, j = 1, 2, \dots, n$ . Then any EIGENVALUE  $\lambda_0$  of  $C$  satisfies the inequality  $|\lambda_0| \leq R$  with the equality sign holding only when there exists an  $n \times n$  MATRIX  $D = \delta_{ij}$  (where  $\delta_{ij}$  is the KRONECKER DELTA) and

$$C = \frac{\lambda_0}{R} D A D^{-1}.$$

#### Wiener Function

see BROWN FUNCTION

#### Wiener-Khintchine Theorem

Recall the definition of the AUTOCORRELATION function  $C(t)$  of a function  $E(t)$ ,

$$C(t) \equiv \int_{-\infty}^{\infty} E^*(\tau) E(t + \tau) d\tau. \quad (1)$$

Also recall that the FOURIER TRANSFORM of  $E(t)$  is defined by

$$E(\tau) = \int_{-\infty}^{\infty} E_\nu e^{-2\pi i \nu \tau} d\nu, \quad (2)$$

giving a COMPLEX CONJUGATE of

$$E^*(\tau) = \int_{-\infty}^{\infty} E_\nu^* e^{2\pi i \nu \tau} d\nu. \quad (3)$$

Plugging  $E^*(\tau)$  and  $E(t + \tau)$  into the AUTOCORRELATION function therefore gives

$$\begin{aligned}
 C(t) &= \int_{-\infty}^{\infty} \left[ \int_{-\infty}^{\infty} E_{\nu}^* e^{2\pi i \nu \tau} d\nu \right] \\
 &\quad \times \left[ \int_{-\infty}^{\infty} E_{\nu'} e^{-2\pi i \nu' (t+\tau)} d\nu' \right] d\tau \\
 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} E_{\nu}^* E_{\nu'} e^{-2\pi i \tau (\nu' - \nu)} e^{-2\pi i \nu' t} d\tau d\nu d\nu' \\
 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} E_{\nu}^* E_{\nu'} \delta(\nu' - \nu) e^{-2\pi i \nu' t} d\nu d\nu' \\
 &= \int_{-\infty}^{\infty} E_{\nu}^* E_{\nu} e^{-2\pi i \nu t} d\nu \\
 &= \int_{-\infty}^{\infty} |E_{\nu}|^2 e^{-2\pi i \nu t} d\nu \\
 &= \mathcal{F}[|E_{\nu}|^2], \tag{4}
 \end{aligned}$$

so, amazingly, the AUTOCORRELATION is simply given by the FOURIER TRANSFORM of the ABSOLUTE SQUARE of  $E(\nu)$ ,

$$C(t) = \mathcal{F}[|E(\nu)|^2]. \tag{5}$$

The Wiener-Khintchine theorem is a special case of the CROSS-CORRELATION THEOREM with  $f = g$ .

see also AUTOCORRELATION, CROSS-CORRELATION THEOREM, FOURIER TRANSFORM

### Wiener Measure

The distribution which arises whenever a central limit scaling procedure is carried out on path-space valued random variables.

### Wiener Space

see MALLIAVIN CALCULUS

### Wigner 3j-Symbol

The Wigner 3j symbols are written

$$\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix} \tag{1}$$

and are sometimes expressed using the related CLEBSCH-GORDON COEFFICIENTS

$$C_{m_1 m_2}^j = (j_1 j_2 m_1 m_2 | j_1 j_2 j m) \tag{2}$$

(Condon and Shortley 1951, pp. 74-75; Wigner 1959, p. 206), or RACAH V-COEFFICIENTS

$$V(j_1 j_2 j; m_1 m_2 m). \tag{3}$$

Connections among the three are

$$\begin{aligned}
 (j_1 j_2 m_1 m_2 | j_1 j_2 j m) \\
 = (-1)^{-j_1 + j_2 - m} \sqrt{2j+1} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \tag{4}
 \end{aligned}$$

$$\begin{aligned}
 (j_1 j_2 m_1 m_2 | j_1 j_2 j m) \\
 = (-1)^{j+m} \sqrt{2j+1} V(j_1 j_2 j; m_1 m_2 -m) \tag{5}
 \end{aligned}$$

$$V(j_1 j_2 j; m_1 m_2 m) = (-1)^{-j_1 + j_2 + j} \begin{pmatrix} j_1 & j_2 & j_1 \\ m_2 & m_1 & m_2 \end{pmatrix}. \tag{6}$$

The Wigner 3j-symbols have the symmetries

$$\begin{aligned}
 \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix} &= \begin{pmatrix} j_2 & j & j_1 \\ m_2 & m & m_1 \end{pmatrix} \\
 &= \begin{pmatrix} j & j_1 & j_2 \\ m & m_1 & m_2 \end{pmatrix} = (-1)^{j_1 + j_2 + j} \begin{pmatrix} j_2 & j_1 & j \\ m_2 & m_1 & m \end{pmatrix} \\
 &= (-1)^{j_1 + j_2 + j} \begin{pmatrix} j_1 & j & j_2 \\ m_1 & m & m_2 \end{pmatrix} \\
 &= (-1)^{j_1 + j_2 + j} \begin{pmatrix} j & j_2 & j_1 \\ m & m_2 & m_1 \end{pmatrix} \\
 &= (-1)^{j_1 + j_2 + j} \begin{pmatrix} j_1 & j_2 & j \\ -m_1 & -m_2 & -m \end{pmatrix}. \tag{7}
 \end{aligned}$$

The symbols obey the orthogonality relations

$$\begin{aligned}
 \sum_{j, m} (2j+1) \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j \\ m'_1 & m'_2 & m \end{pmatrix} \\
 = \delta_{m_1 m'_1} \delta_{m_2 m'_2} \tag{8}
 \end{aligned}$$

$$\sum_{m_1, m_2} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & m \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j' \\ m_1 & m_2 & m' \end{pmatrix} = \delta_{jj'} \delta_{m_1 m'_1}, \tag{9}$$

where  $\delta_{ij}$  is the KRONECKER DELTA.

General formulas are very complicated, but some specific cases are

$$\begin{aligned}
 \begin{pmatrix} j_1 & j_2 & j_1 + j_2 \\ m_1 & m_2 & -m_1 - m_2 \end{pmatrix} &= (-1)^{j_1 - j_2 + m_1 + m_2} \\
 &\times \left[ \frac{(2j_1)!(2j_2)!}{(2j_1 + 2j_2 + 1)!(j_1 + m_1)!} \right. \\
 &\quad \times \left. \frac{(j_1 + j_2 + m_1 + m_2)!(j_1 + j_2 - m_1 - m_2)!}{(j_1 - m_1)!(j_2 + m_2)!(j_2 - m_2)!} \right]^{1/2} \tag{10}
 \end{aligned}$$

$$\begin{aligned}
 \begin{pmatrix} j_1 & j_2 & j \\ j_1 & -j_1 - & m \end{pmatrix} &= (-1)^{-j_1 + j_2 + m} \\
 &\times \left[ \frac{(2j_1)!(-j_1 + j_2 + j)!}{(j_1 + j_2 + j + 1)!(j_1 - j_2 + j)!} \right. \\
 &\quad \times \left. \frac{(j_1 + j_2 + m)!(j - m)!}{(j_1 + j_2 - j)!(-j_1 + j_2 - m)!(j + m)!} \right]^{1/2} \tag{11}
 \end{aligned}$$

$$\begin{pmatrix} j_1 & j_2 & j \\ 0 & 0 & 0 \end{pmatrix} = \begin{cases} (-1)^g \sqrt{\frac{(2g-2j_1)(2g-2j_2)!(2g-2j)!}{(2g+1)!}} \frac{g!}{(g-j_1)!(g-j_2)!(g-j)!} & \text{if } J = 2g \\ 0 & \text{if } J = 2g + 1, \end{cases} \quad (12)$$

for  $J \equiv j_1 + j_2 + j$ .

For SPHERICAL HARMONICS  $Y_{lm}(\theta, \phi)$ ,

$$\begin{aligned} & Y_{l_1 m_1}(\theta, \phi) Y_{l_2 m_2}(\theta, \phi) \\ &= \sum_{l, m} \sqrt{\frac{(2l_1+1)(2l_2+1)(2l+1)}{4\pi}} \begin{pmatrix} l_1 & l_2 & l \\ m_1 & m_2 & m \end{pmatrix} \\ & \quad \times Y_{lm}^*(\theta, \phi) \begin{pmatrix} l_1 & l_2 & l \\ 0 & 0 & 0 \end{pmatrix}. \quad (13) \end{aligned}$$

For values of  $l_3$  obeying the TRIANGLE CONDITION  $\Delta(l_1 l_2 l_3)$ ,

$$\begin{aligned} & \int Y_{l_1 m_1}(\theta, \phi) Y_{l_2 m_2}(\theta, \phi) Y_{l_3 m_3}(\theta, \phi) \sin \theta d\theta d\phi \\ &= \sqrt{\frac{(2l_1+1)(2l_2+1)(2l_3+1)}{4\pi}} \\ & \quad \times \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l_1 & l_2 & l_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \quad (14) \end{aligned}$$

and

$$\begin{aligned} & \frac{1}{2} \int P_{l_1}(\cos \theta) P_{l_2}(\cos \theta) P_{l_3}(\cos \theta) \sin \theta d\theta \\ &= \begin{pmatrix} l_1 & l_2 & l_3 \\ 0 & 0 & 0 \end{pmatrix}^2. \quad (15) \end{aligned}$$

#### Wigner 6j-Symbol

A generalization of CLEBSCH-GORDON COEFFICIENTS and WIGNER 3j-SYMBOL which arises in the coupling of three angular momenta. Let tensor operators  $T^{(k)}$  and  $U^{(k)}$  act, respectively, on subsystems 1 and 2 of a system, with subsystem 1 characterized by angular momentum  $\mathbf{j}_1$  and subsystem 2 by the angular momentum  $\mathbf{j}_2$ . Then the matrix elements of the scalar product of these two tensor operators in the coupled basis  $\mathbf{J} = \mathbf{j}_1 + \mathbf{j}_2$  are given by

$$\begin{aligned} & (\tau'_1 j'_1 \tau'_2 j'_2 J' M' | T^{(k)} \cdot U^{(k)} | \tau_1 j_1 \tau_2 j_2 J M) \\ &= \delta_{JJ'} \delta_{MM'} (-1)^{j_1+j'_2+J} \begin{Bmatrix} J & j'_2 & j'_1 \\ k & j_1 & j_2 \end{Bmatrix} \\ & \quad \times (\tau'_1 j'_1 || T^{(k)} || \tau_1 j_1) (\tau'_2 j'_2 || U^{(k)} || \tau_2 j_2), \quad (1) \end{aligned}$$

where  $\begin{Bmatrix} J & j'_2 & j'_1 \\ k & j_1 & j_2 \end{Bmatrix}$  is the Wigner 6j-symbol and  $\tau_1$  and  $\tau_2$  represent additional pertinent quantum numbers characterizing subsystems 1 and 2 (Gordy and Cook 1984).

Edmonds (1968) gives analytic forms of the 6j-symbol for simple cases, and Shore and Menzel (1968) and Gordy and Cook (1984) give

$$\begin{Bmatrix} a & b & c \\ 0 & c & b \end{Bmatrix} = \frac{(-1)^s}{\sqrt{(2b+1)(2c+1)}} \quad (2)$$

$$\begin{Bmatrix} a & b & c \\ 1 & c & b \end{Bmatrix} = \frac{2(-1)^{s+1}X}{\sqrt{2b(2b+1)(2b+2)2c(2c+1)(2c+2)}} \quad (3)$$

$$\begin{aligned} & \begin{Bmatrix} a & b & c \\ 2 & c & b \end{Bmatrix} = \frac{2(-1)^s [3X(X-1) - 4b(b+1)c(c+1)]}{\sqrt{(2b-1)2b(2b+1)(2b+2)(2b+3)}} \\ & \quad \times \frac{1}{\sqrt{(2c-1)2c(2c+1)(2c+2)(2c+3)}}, \quad (4) \end{aligned}$$

where

$$s \equiv a + b + c \quad (5)$$

$$X \equiv b(b+1) + c(c+1) - a(a+1). \quad (6)$$

### Wigner 9j-Symbol

A generalization of CLEBSCH-GORDON COEFFICIENTS and WIGNER 3j- and 6j-SYMBOLS which arises in the coupling of four angular momenta and can be written in terms of the WIGNER 3j- and 6j-SYMBOLS. Let tensor operators  $T^{(k_1)}$  and  $U^{(k_2)}$  act, respectively, on subsystems 1 and 2. Then the reduced matrix element of the product  $T^{(k_1)} \times U^{(k_2)}$  of these two irreducible operators in the coupled representation is given in terms of the reduced matrix elements of the individual operators in the uncoupled representation by

$$(\tau' \tau'_1 j'_1 \tau'_2 j'_2 J' || [T^{(k_1)} \times U^{(k_2)}]^{(k)} || \tau \tau_1 j_1 \tau_2 j_2 J) \\ = \sqrt{(2J+1)(2J'+1)(2k+1)} \sum_{\tau''} \begin{Bmatrix} j'_1 & j_1 & k_1 \\ j'_2 & j_2 & k_2 \\ J' & J & k \end{Bmatrix} \\ (\tau' \tau'_1 j'_1 || T^{(k_1)} || \tau'' \tau_1 j_1) (\tau'' \tau'_2 j'_2 || U^{(k_2)} || \tau \tau_2 j_2), \quad (1)$$

where  $\begin{Bmatrix} j'_1 & j_1 & k_1 \\ j'_2 & j_2 & k_2 \\ J' & J & k \end{Bmatrix}$  is a Wigner 9j-symbol (Gordy and Cook 1984).

Shore and Menzel (1968) give the explicit formulas

$$\begin{Bmatrix} a & b & C \\ d & e & F \\ G & H & J \end{Bmatrix} = \sum_x (-1)^{2x} (2x+1) \\ \times \begin{Bmatrix} a & b & C \\ F & J & x \end{Bmatrix} \begin{Bmatrix} d & e & F \\ b & x & H \end{Bmatrix} \begin{Bmatrix} G & H & J \\ x & a & d \end{Bmatrix} \quad (2)$$

$$\begin{Bmatrix} a & b & J \\ c & d & J \\ K & K & 0 \end{Bmatrix} = \frac{(-1)^{b+c+J+K}}{\sqrt{(2J+1)(2K+1)}} \begin{Bmatrix} a & b & J \\ d & c & K \end{Bmatrix} \quad (3)$$

$$\begin{Bmatrix} S & S & 1 \\ L & L & 2 \\ J & J & 1 \end{Bmatrix} = \frac{\begin{Bmatrix} S & L & J \\ L & S & 1 \end{Bmatrix} \begin{Bmatrix} J & L & S \\ L & J & 1 \end{Bmatrix}}{5 \begin{Bmatrix} 2 & L & L \\ L & 1 & 1 \end{Bmatrix}} \\ + \frac{(-1)^{S+L+J+1}}{15(2L+1)} \begin{Bmatrix} S & J & L \\ J & S & 1 \end{Bmatrix} \begin{Bmatrix} 2 & L & L \\ L & 1 & 1 \end{Bmatrix}. \quad (4)$$

### Wigner-Eckart Theorem

A theorem of fundamental importance in spectroscopy and angular momentum theory which provides both (1) an explicit form for the dependence of all matrix elements of irreducible tensors on the projection quantum numbers and (2) a formal expression of the conservation laws of angular momentum (Rose 1995).

The theorem states that the dependence of the matrix element  $(j' m' | T_{LM} | j m)$  on the projection quantum numbers is entirely contained in the WIGNER 3j-SYMBOL (or, equivalently, the CLEBSCH-GORDON COEFFICIENT), given by

$$(j' m' | T_{LM} | j m) = C(j L j'; m M m') (j' | T_L | j),$$

where  $C(j L j'; m M m')$  is a CLEBSCH-GORDON COEFFICIENT and  $T_{LM}$  is a set of tensor operators (Rose 1995, p. 85).

**Wilbraham-Gibbs Constant**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let a piecewise smooth function  $f$  with only finitely many discontinuities (which are all jumps) be defined on  $[-\pi, \pi]$  with FOURIER SERIES

$$a_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f(t) \cos(kt) dt \quad (1)$$

$$b_k = \frac{1}{\pi} \int_{-\pi}^{\pi} f(t) \sin(kt) dt, \quad (2)$$

$$S_n(f, x) = \frac{1}{2}a_0 + \left\{ \sum_{k=1}^n [a_k \cos(kx) + b_k \sin(kx)] \right\}. \quad (3)$$

Let a discontinuity be at  $x = c$ , with

$$\lim_{x \rightarrow c^-} f(x) > \lim_{x \rightarrow c^+} f(x), \quad (4)$$

so

$$D \equiv \left[ \lim_{x \rightarrow c^-} f(x) \right] - \left[ \lim_{x \rightarrow c^+} f(x) \right] > 0. \quad (5)$$

Define

$$\phi(c) = \frac{1}{2} \left[ \lim_{x \rightarrow c^-} f(x) + \lim_{x \rightarrow c^+} f(x) \right], \quad (6)$$

and let  $x = x_n < c$  be the first local minimum and  $x = \xi_n > c$  the first local maximum of  $S_n(f, x)$  on either side of  $x_n$ . Then

$$\lim_{n \rightarrow \infty} S_n(f, x_n) = \phi(c) + \frac{D}{\pi} G' \quad (7)$$

$$\lim_{n \rightarrow \infty} S_n(f, \xi_n) = \phi(c) - \frac{D}{\pi} G', \quad (8)$$

where

$$G' \equiv \int_0^{\pi} \operatorname{sinc} \theta d\theta = 1.851937052\dots \quad (9)$$

Here,  $\operatorname{sinc} x \equiv \sin x/x$  is the SINC FUNCTION. The FOURIER SERIES of  $y = x$  therefore does not converge to  $-\pi$  and  $\pi$  at the ends, but to  $-2G'$  and  $2G'$ . This phenomenon was observed by Wilbraham (1848) and Gibbs (1899). Although Wilbraham was the first to note the phenomenon, the constant  $G'$  is frequently (and unfairly) credited to Gibbs and known as the GIBBS CONSTANT. A related constant sometimes also called the GIBBS CONSTANT is

$$G \equiv \frac{2}{\pi} G' = \frac{2}{\pi} \int_0^{\pi} \operatorname{sinc} x dx = 1.17897974447216727\dots \quad (10)$$

(Le Lionnais 1983).

**Wilcoxon Rank Sum Test**

A nonparametric alternative to the two-sample  $t$ -test.

see also PAIRED  $t$ -TEST, PARAMETRIC TEST

**Wilcoxon Signed Rank Test**

A nonparametric alternative to the PAIRED  $t$ -TEST which is similar to the FISHER SIGN TEST. This test assumes that there is information in the magnitudes of the differences between paired observations, as well as the signs. Take the paired observations, calculate the differences, and rank them from smallest to largest by ABSOLUTE VALUE. Add all the ranks associated with POSITIVE differences, giving the  $T_+$  statistic. Finally, the  $P$ -VALUE associated with this statistic is found from an appropriate table. The Wilcoxon test is an  $R$ -ESTIMATE.

see also FISHER SIGN TEST, HYPOTHESIS TESTING, PAIRED  $t$ -TEST, PARAMETRIC TEST

**Wild Knot**

A KNOT which is not a TAME KNOT.

see also TAME KNOT

**References**

- Milnor, J. "Most Knots are Wild." *Fund. Math.* **54**, 335–338, 1964.

**Wild Point**

For any point  $P$  on the boundary of an ordinary BALL, find a NEIGHBORHOOD of  $P$  in which the intersection with the BALL's boundary cuts the NEIGHBORHOOD into two parts, each HOMEOMORPHIC to a BALL. A wild point is a point on the boundary that has no such NEIGHBORHOOD.

see also BALL, HOMEOMORPHIC, NEIGHBORHOOD

**Wilf-Zeilberger Pair**

A pair of CLOSED FORM functions  $(F, G)$  is said to be a Wilf-Zeilberger pair if

$$F(n+1, k) - F(n, k) = G(n, k+1) - G(n, k). \quad (1)$$

The Wilf-Zeilberger formalism provides succinct proofs of *known* identities and allows new identities to be discovered whenever it succeeds in finding a proof certificate for a known identity. However, if the starting point is an unknown hypergeometric sum, then the Wilf-Zeilberger method cannot discover a closed form solution, while ZEILBERGER'S ALGORITHM can.

Wilf-Zeilberger pairs are very useful in proving HYPERGEOMETRIC IDENTITIES of the form

$$\sum_k t(n, k) = \operatorname{rhs}(n) \quad (2)$$

for which the SUMMAND  $t(n, k)$  vanishes for all  $k$  outside some finite interval. Now divide by the right-hand side to obtain

$$\sum_k F(n, k) = 1, \quad (3)$$

where

$$F(n, k) \equiv \frac{t(n, k)}{\text{rhs}(n)}. \quad (4)$$

Now use a RATIONAL FUNCTION  $R(n, k)$  provided by ZEILBERGER'S ALGORITHM, define

$$G(n, k) \equiv R(n, k)F(n, k). \quad (5)$$

The identity (1) then results. Summing the relation over all integers then telescopes the right side to 0, giving

$$\sum_k F(n+1, k) = \sum_k F(n, k). \quad (6)$$

Therefore,  $\sum_k F(n, k)$  is independent of  $n$ , and so must be a constant. If  $F$  is properly normalized, then it will be true that  $\sum_k F(0, k) = 1$ .

For example, consider the BINOMIAL COEFFICIENT identity

$$\sum_k = \sum_{k=0}^n \binom{n}{k} = 2^n, \quad (7)$$

the function  $R(n, k)$  returned by ZEILBERGER'S ALGORITHM is

$$R(n, k) = \frac{k}{2(k-n-1)}. \quad (8)$$

Therefore,

$$F(n, k) = \binom{n}{k} 2^{-n} \quad (9)$$

and

$$\begin{aligned} G(n, k) &\equiv R(n, k)F(n, k) = \frac{k}{2(k-n-1)} \binom{n}{k} 2^{-n} \\ &= -\frac{kn!2^{-n}}{2(n+1-k)k!(n-k)!} = -\binom{n}{k-1} 2^{-n-1}. \end{aligned} \quad (10)$$

Taking

$$F(n+1, k) - F(n, k) = G(n, k+1) - G(n, k) \quad (11)$$

then gives the alleged identity

$$\begin{aligned} \binom{n+1}{k} 2^{-n-1} - \binom{n}{k} 2^{-n} \\ = -\binom{n}{k} 2^{-n-1} + \binom{n}{k-1} 2^{-n-1} \end{aligned} \quad (12)$$

Expanding and evaluating shows that the identity does actually hold, and it can also be verified that

$$F(0, k) = \binom{0}{k} = \begin{cases} 1 & \text{for } k = 0 \\ 0 & \text{otherwise,} \end{cases} \quad (13)$$

so  $\sum_k F(0, k) = 1$  (Petkovšek *et al.* 1996, pp. 25–27).

For any Wilf-Zeilberger pair  $(F, G)$ ,

$$\sum_{n=0}^{\infty} G(n, 0) = \sum_{n=1}^{\infty} [F(n, n-1) + G(n-1, n-1)] \quad (14)$$

whenever either side converges (Zeilberger 1993). In addition,

$$\sum_{n=0}^{\infty} G(n, 0) = \sum_{n=0}^{\infty} \left[ F(s(n+1), n) + \sum_{i=0}^{s-1} G(sn+i, n) \right], \quad (15)$$

$$\sum_{k=0}^{\infty} F(0, k) = \sum_{n=0}^{\infty} G(n, 0), \quad (16)$$

and

$$\begin{aligned} \sum_{n=0}^{\infty} G(n, 0) &= \sum_{n=0}^{\infty} \left[ \sum_{j=0}^{t-1} F(s(n+1), tn+j) \right. \\ &\quad \left. + \sum_{i=0}^{s-1} G(sn+i, tn) \right], \end{aligned} \quad (17)$$

where

$$F_{s,t}(n, k) = \sum_{j=0}^{t-1} F(sn, tk+j) \quad (18)$$

$$G_{s,t}(n, k) = \sum_{i=0}^{s-1} G(sn+i, tk) \quad (19)$$

(Amdeberhan and Zeilberger 1997). The latter identity has been used to compute APÉRY'S CONSTANT to a large number of decimal places (Plouffe).

**Wilkie's Theorem**

Let  $\phi(x_1, \dots, x_n)$  be an  $\mathcal{L}_{\text{exp}}$  formula, where  $\mathcal{L}_{\text{exp}} = \mathcal{L} \cup \{e^x\}$  and  $\mathcal{L}$  is the language of ordered rings  $\mathcal{L} = \{+, -, \cdot, <, 0, 1\}$ . Then there are  $n \geq m$  and  $f_1, \dots, f_s \in \mathbb{Z}[x_1, \dots, x_n, e^{x_1}, \dots, e^{x_n}]$  such that  $\phi(x_1, \dots, x_n)$  is equivalent to

$$\exists x_{m+1} \cdots \exists x_n f_1(x_1, \dots, x_n, e^{x_1}, \dots, e^{x_n}) = \dots \\ = f_s(x_1, \dots, x_n, e^{x_1}, \dots, e^{x_n}) = 0$$

(Wilkie 1996). In other words, every formula is equivalent to an existential formula and every definable set is the projection of an exponential variety (Marker 1996).

**Wilson Plug**

A 3-D surface with constant VECTOR FIELD on its boundary which traps at least one trajectory which enters it.

see also VECTOR FIELD

**Wilson's Primality Test**

see WILSON'S THEOREM

**Wilson Prime**

A PRIME satisfying

$$W(p) \equiv 0 \pmod{p},$$

where  $W(p)$  is the WILSON QUOTIENT, or equivalently,

$$(p-1)! \equiv -1 \pmod{p^2}.$$

5, 13, and 563 are the only Wilson primes less than  $5 \times 10^8$  (Crandall *et al.* 1997).

**References**

 Vardi, I. *Computational Recreations in Mathematica*. Reading, MA: Addison-Wesley, p. 73, 1991.

**Wilson Quotient**

$$W(p) \equiv \frac{(p-1)! - 1}{p}.$$

**Wilson's Theorem**

IFF  $p$  is a PRIME, then  $(p-1)! + 1$  is a multiple of  $p$ , that is

$$(p-1)! \equiv -1 \pmod{p}.$$

This theorem was proposed by John Wilson in 1770 and proved by Lagrange in 1773. Unlike FERMAT'S LITTLE THEOREM, Wilson's theorem is both NECESSARY and SUFFICIENT for primality. For a COMPOSITE NUMBER,  $(n-1)! \equiv 0 \pmod{n}$  except when  $n = 4$ .

see also FERMAT'S LITTLE THEOREM, WILSON'S THEOREM COROLLARY, WILSON'S THEOREM (GAUSS'S GENERALIZATION)

**References**

**Wilson's Theorem Corollary**

Iff a PRIME  $p$  is of the form  $4x + 1$ , then

$$[(2x)!]^2 \equiv -1 \pmod{p}.$$

**Wilson's Theorem (Gauss's Generalization)**

Let  $P$  be the product of INTEGERS less than or equal to  $n$  and RELATIVELY PRIME to  $n$ . Then

$$P \equiv \prod_{\substack{k=2 \\ k \nmid n}}^n = \begin{cases} -1 \pmod{n} & \text{for } n = 4, p^\alpha, 2p^\alpha \\ 1 \pmod{n} & \text{otherwise.} \end{cases}$$

When  $m = 2$ , this reduces to  $P \equiv 1 \pmod{2}$  which is equivalent to  $P \equiv -1 \pmod{2}$ .

see also WILSON'S THEOREM, WILSON'S THEOREM COROLLARY

**Winding Number (Contour)**

Denoted  $n(\gamma, z_0)$  and defined as the number of times a path  $\gamma$  curve passes around a point.

$$n(\gamma, a) = \frac{1}{2\pi i} \int_{\gamma} \frac{dz}{z - a}.$$

The contour winding number was part of the inspiration for the idea of the DEGREE of a MAP between two COMPACT, oriented MANIFOLDS of the same DIMENSION. In the language of the DEGREE of a MAP, if  $\gamma : [0, 1] \rightarrow \mathbb{C}$

is a closed curve (i.e.,  $\gamma(0) = \gamma(1)$ ), then it can be considered as a FUNCTION from  $\mathbb{S}^1$  to  $\mathbb{C}$ . In that context, the winding number of  $\gamma$  around a point  $p$  in  $\mathbb{C}$  is given by the degree of the MAP

$$\frac{\gamma - p}{|\gamma - p|}$$

from the CIRCLE to the CIRCLE.

### Winding Number (Map)

The winding number of a map is defined by

$$W \equiv \lim_{n \rightarrow \infty} \frac{f^n(\theta) - \theta}{n},$$

which represents the average increase in the angle  $\theta$  per unit time (average frequency). A system with a RATIONAL winding number  $W = p/q$  is MODE-LOCKED, whereas a system with an IRRATIONAL winding number is QUASIPERIODIC. Note that since the RATIONALS are a set of zero MEASURE on any finite interval, almost all winding numbers will be irrational, so almost all maps will be QUASIPERIODIC.

### Windmill

One name for the figure used by Euclid to prove the PYTHAGOREAN THEOREM.

see BRIDE'S CHAIR, PEACOCK'S TAIL

### Window Function

see RECTANGLE FUNCTION

### Winkler Conditions

Conditions arising in the study of the ROBBINS EQUATION and its connection with BOOLEAN ALGEBRA. Winkler studied Boolean conditions (such as idempotence or existence of a zero) which would make a ROBBINS ALGEBRA become a BOOLEAN ALGEBRA. Winkler showed that each of the conditions

$$\exists C, \exists D, C + D = C$$

$$\exists C, \exists D, n(C + D) = n(C),$$

known as the first and second Winkler conditions, SUFFICES. A computer proof demonstrated that every ROBBINS ALGEBRA satisfies the second Winkler condition, from which it follows immediately that all ROBBINS ALGEBRAS are BOOLEAN.

### Witch of Agnesi

A curve studied and named "versiera" (Italian for "she-devil" or "witch") by Maria Agnesi in 1748 in her book *Istituzioni Analitiche* (MacTutor Archive). It is also known as CUBIQUE D'AGNESI or AGNÉSIENNNE. Some suggest that Agnesi confused an old Italian word meaning "free to move" with another meaning "witch." The curve had been studied earlier by Fermat and Guido Grandi in 1703.

It is the curve obtained by drawing a line from the origin through the CIRCLE of radius  $2a$  ( $OB$ ), then picking the point with the  $y$  coordinate of the intersection with the circle and the  $x$  coordinate of the intersection of the extension of line  $OB$  with the line  $y = 2a$ . The curve

has INFLECTION POINTS at  $y = 3a/2$ . The line  $y = 0$  is an ASYMPTOTE to the curve.

In parametric form,

$$x = 2a \cot \theta \quad (1)$$

$$y = a[1 - \cos(2\theta)], \quad (2)$$

or

$$x = 2at \quad (3)$$

$$y = \frac{2a}{1+t^2}. \quad (4)$$

In rectangular coordinates,

$$y = \frac{8a^3}{x^2 + 4a^2}. \quad (5)$$

#### Witness

A witness is a number which, as a result of its number theoretic properties, guarantees either the compositeness or primality of a number  $n$ . Witnesses are most commonly used in connection with FERMAT'S LITTLE THEOREM CONVERSE. A PRATT CERTIFICATE uses witnesses to prove primality, and MILLER'S PRIMALITY TEST uses witnesses to prove compositeness.

see also ADLEMAN-POMERANCE-RUMELY PRIMALITY TEST, FERMAT'S LITTLE THEOREM CONVERSE, MILLER'S PRIMALITY TEST, PRATT CERTIFICATE, PRIMALITY CERTIFICATE

#### Witten's Equations

Also called the SEIBERG-WITTEN INVARIANTS. For a connection  $A$  and a POSITIVE SPINOR  $\phi \in \Gamma(V_+)$ ,

$$\begin{aligned} D_A \phi &= 0 \\ F_+^A &= i\sigma(\phi, \phi). \end{aligned}$$

The solutions are called monopoles and are the minima of the functional

$$\int_X (|F_+^A - i\sigma(\phi, \phi)|^2 + |D_A \phi|^2).$$

#### Wittenbauer's Parallelogram

Divide the sides of a QUADRILATERAL into three equal parts. The figure formed by connecting and extending adjacent points on either side of a VERTEX is a PARALLELOGRAM known as Wittenbauer's parallelogram.

see also QUADRILATERAL, WITTENBAUER'S THEOREM

#### Wittenbauer's Theorem

The CENTROID of a QUADRILATERAL LAMINA is the center of its WITTENBAUER'S PARALLELOGRAM.

see also CENTROID (GEOMETRIC), LAMINA, QUADRILATERAL, WITTENBAUER'S PARALLELOGRAM

#### Wolstenholme's Theorem

If  $p$  is a PRIME  $> 3$ , then the NUMERATOR of

$$1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{p-1}$$

is divisible by  $p^2$  and the NUMERATOR of

$$1 + \frac{1}{2^2} + \frac{1}{3^2} + \dots + \frac{1}{(p-1)^2}$$

is divisible by  $p$ . These imply that if  $p \geq 5$  is PRIME, then

$$\binom{2p-1}{p-1} \equiv 1 \pmod{p^3}.$$

**Woodbury Formula**

$$(A + UV^T)^{-1} = A^{-1} - [A^{-1}U(1 + V^T A^{-1}U)^{-1}V^T A^{-1}].$$

**Word**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

A finite sequence of  $n$  letters from some ALPHABET is said to be an  $n$ -ary word. A "square" word consists of two identical subwords (for example, *acbacb*). A square-free word contains no square words as subwords (for example, *abcacbabcb*). The only squarefree binary words are *a*, *b*, *ab*, *ba*, *aba*, and *bab*. However, there are arbitrarily long ternary squarefree words. The number of ternary squarefree words of length  $n$  is bounded by

$$6 \cdot 1.032^n \leq s(n) \leq 6 \cdot 1.379^n \quad (1)$$

(Brandenburg 1983). In addition,

$$S \equiv \lim_{n \rightarrow \infty} [s(n)]^{1/n} = 1.302 \dots \quad (2)$$

(Brinkhuis 1983, Noonan and Zeilberger). Binary cube-free words satisfy

$$2 \cdot 1.080^n \leq c(n) \leq 2 \cdot 1.522^n. \quad (3)$$

A word is said to be overlapfree if it has no subwords of the form *xyxyx*. A squarefree word is overlapfree, and an

overlapfree word is cube-free. The number  $t(n)$  of binary overlapfree words of length  $n$  satisfies

$$p \cdot n^{1.155} \leq t(n) \leq q \cdot n^{1.587} \quad (4)$$

for some constants  $p$  and  $q$  (Restivo and Selemi 1985, Kobayashi 1988). In addition, while

$$\lim_{n \rightarrow \infty} \frac{\ln t(n)}{\ln n} \quad (5)$$

does not exist,

$$1.155 < T_L < 1.276 < 1.332 < T_U < 1.587, \quad (6)$$

where

$$T_L \equiv \liminf_{n \rightarrow \infty} \frac{\ln t(n)}{\ln n} \quad (7)$$

$$T_U \equiv \limsup_{n \rightarrow \infty} \frac{\ln t(n)}{\ln n} \quad (8)$$

(Cassaigne 1993).

**Worpitzky's Identity**

$$x^n = \sum_{k=0}^{n-1} \left\langle \begin{matrix} n \\ k \end{matrix} \right\rangle \binom{n+k}{n},$$

where  $\left\langle \begin{matrix} n \\ k \end{matrix} \right\rangle$  is an EULERIAN NUMBER and  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT.

**Writhe**

Also called the TWIST NUMBER. The sum of crossings  $p$  of a LINK  $L$ ,

$$w(L) = \sum_{p \in C(L)} \epsilon(p),$$

where  $\epsilon(p)$  defined to be  $\pm 1$  if the overpass slants from top left to bottom right or bottom left to top right and  $C(L)$  is the set of crossings of an oriented LINK. If a KNOT  $K$  is AMPHICHIRAL, then  $w(K) = 0$  (Thistlethwaite). Letting  $Lk$  be the LINKING NUMBER of the two components of a ribbon,  $Tw$  be the TWIST, and  $Wr$  be the writhe, then

$$Lk(K) = Tw(K) + Wr(K).$$

(Adams 1994, p. 187).

see also SCREW, TWIST

**Wythoff Symbol**

A symbol used to describe UNIFORM POLYHEDRA. For example, the Wythoff symbol for the TETRAHEDRON is  $3|23$ . There are three types of Wythoff symbols  $p|qr$ ,  $pq|r$  and  $pqr|$ , and one exceptional symbol  $|\frac{3}{2}\frac{5}{3}3\frac{5}{2}$  used for the GREAT DIRHOMBICOSIDODECAHEDRON. Some special cases in terms of SCHLÄFLI SYMBOLS are

$$p|q2 = p|2q = \{q, p\}$$

$$2|pq = \left\{ \begin{matrix} p \\ q \end{matrix} \right\}$$

$$pq|2 = r \left\{ \begin{matrix} p \\ q \end{matrix} \right\}$$

$$2q|p = t\{p, q\}$$

$$2pq| = t \left\{ \begin{matrix} p \\ q \end{matrix} \right\}$$

$$|2pq = s \left\{ \begin{matrix} p \\ q \end{matrix} \right\}.$$

For the symbol  $pqr|$ , permuting the letters gives the same POLYHEDRON.

*see also* UNIFORM POLYHEDRON

Har'El, Z. "Uniform Solution for Uniform Polyhedra." *Geometriae Dedicata* **47**, 57–110, 1993.

x-Axis

# X

x-Axis

The horizontal axis of a 2-D plot in CARTESIAN COORDINATES, also called the ABSCISSA.

see also ABSCISSA, ORDINATE, y-AXIS, z-AXIS

x-Intercept

The point at which a curve or function crosses the x-AXIS (i.e., when  $y = 0$  in 2-D).

see also LINE, y-INTERCEPT

Xi Function

$$\xi(z) \equiv \frac{1}{2}z(z-1)\frac{\Gamma(\frac{1}{2}z)}{\pi^{z/2}}\zeta(z) = \frac{(z-1)\Gamma(\frac{1}{2}z+1)\zeta(z)}{\sqrt{\pi}z}, \quad (1)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION and  $\Gamma(z)$  is the GAMMA FUNCTION (Gradshteyn and Ryzhik 1980, p. 1076). The  $\xi$  function satisfies the identity

$$\xi(1-z) = \xi(z). \quad (2)$$

The zeros of  $\xi(z)$  and of its DERIVATIVES are all located on the CRITICAL STRIP  $z = \sigma + it$ , where  $0 < \sigma < 1$ . Therefore, the nontrivial zeros of the RIEMANN ZETA FUNCTION exactly correspond to those of  $\xi(z)$ . The function  $\xi(z)$  is related to what Gradshteyn and Ryzhik (1980, p. 1074) call  $\Xi(t)$  by

$$\Xi(t) \equiv \xi(z), \quad (3)$$

where  $z \equiv \frac{1}{2} + it$ . This function can also be defined as

$$\Xi(it) \equiv \frac{1}{2}(t^2 - \frac{1}{4})\pi^{-t/2-1/4}\Gamma(\frac{1}{2}t + \frac{1}{4})\zeta(t + \frac{1}{2}), \quad (4)$$

giving

$$\Xi(t) = -\frac{1}{2}(t^2 + \frac{1}{4})\pi^{it/2-1/4}\Gamma(\frac{1}{4} - \frac{1}{2}it)\zeta(\frac{1}{2} - it). \quad (5)$$

The DE BRUIJN-NEWMAN CONSTANT is defined in terms of the  $\Xi(t)$  function.

see also DE BRUIJN-NEWMAN CONSTANT

## Yanghui Triangle

see PASCAL'S TRIANGLE

## Yff Center of Congruence

Let three ISOSCELES, one for each side, be constructed on a TRIANGLE such that the four interior triangles they determine are congruent. Now parallel-displace these ISOSCELES until they concur in a single point. This point is called the Yff center of congruence and has TRIANGLE CENTER FUNCTION

$$\alpha = \sec(\frac{1}{2}A).$$

see also CONGRUENT ISOSCELES POINT, ISOSCELESIZER

## References

Kimberling, C. "Yff Center of Congruence." <http://www.evansville.edu/~ck6/tcenters/recent/yffcc.html>.

## Yff Points

Let points  $A'$ ,  $B'$ , and  $C'$  be marked off some fixed distance  $x$  along each of the sides  $BC$ ,  $CA$ , and  $AB$ . Then the lines  $AA'$ ,  $BB'$ , and  $CC'$  concur in a point  $U$  known as the first Yff point if

$$x^3 = (a-x)(b-x)(c-x). \quad (1)$$

This equation has a single real root  $u$ , which can be obtained by solving the CUBIC EQUATION

$$f(x) = 2x^3 - px^2 + qx - r = 0, \quad (2)$$

where

$$p = a + b + c \quad (3)$$

$$q = ab + ac + bc \quad (4)$$

$$r = abc. \quad (5)$$

The ISOTOMIC CONJUGATE POINT  $U'$  is called the second Yff point. The TRIANGLE CENTER FUNCTIONS of the first and second points are given by

$$\alpha = \frac{1}{a} \left( \frac{c-u}{b-u} \right)^{1/3} \quad (6)$$

and

$$\alpha' = \frac{1}{a} \left( \frac{b-u}{c-u} \right)^{1/3}, \quad (7)$$

respectively. Analogous to the inequality  $\omega \leq \pi/6$  for the BROCARD ANGLE  $\omega$ ,  $u \leq p/6$  holds for the Yff points, with equality in the case of an EQUILATERAL TRIANGLE. Analogous to

$$\omega < \alpha_i < \pi - 3\omega \quad (8)$$

for  $i = 1, 2, 3$ , the Yff points satisfy

$$u < a_i < p - 3u. \quad (9)$$

Yff (1963) gives a number of other interesting properties. The line  $UU'$  is PERPENDICULAR to the line containing the INCENTER  $I$  and CIRCUMCENTER  $O$ , and its length is given by

$$\overline{UU'} = \frac{4u\overline{IO}\Delta}{u^3 + abc}, \quad (10)$$

where  $\Delta$  is the AREA of the TRIANGLE.

see also BROCARD POINTS, YFF TRIANGLES

## References

Yff, P. "An Analog of the Brocard Points." *Amer. Math. Monthly* **70**, 495-501, 1963.

## Yff Triangles

The TRIANGLE  $\Delta A'B'C'$  formed by connecting the points used to construct the YFF POINTS is called the first Yff triangle. The AREA of the triangle is

$$\Delta = \frac{u^3}{2R},$$

where  $R$  is the CIRCUMRADIUS of the original TRIANGLE  $\Delta ABC$ . The second Yff triangle is formed by connecting the ISOTOMIC CONJUGATE POINTS of  $A'$ ,  $B'$ , and  $C'$ .

## Yin-Yang

A figure used in many Asian cultures to symbolize the unity of the two "opposite" male and female elements, the "yin" and "yang." The solid and hollow parts composing the symbol are similar and combine to make a CIRCLE. Each part consists of two equal oppositely oriented SEMICIRCLES of radius  $1/2$  joined at their edges, plus a SEMICIRCLE of radius  $1$  joining the other edges.

see also BASEBALL COVER, CIRCLE, PIECEWISE CIRCULAR CURVE, SEMICIRCLE

## Young Diagram

A Young diagram, also called a FERRERS DIAGRAM, represents PARTITIONS as patterns of dots, with the  $n$ th row having the same number of dots as the  $n$ th term in the PARTITION. A Young diagram of the PARTITION

$$n = a + b + \dots + c,$$

for a list  $a, b, \dots, c$  of  $k$  POSITIVE INTEGERS with  $a \geq b \geq \dots \geq c$  is therefore the arrangement of  $n$  dots or square boxes in  $k$  rows, such that the dots or boxes are left-justified, the first row is of length  $a$ , the second row is of length  $b$ , and so on, with the  $k$ th row of length  $c$ . The above diagram corresponds to one of the possible partitions of 100.

## Young Inequality

For  $0 < p < 1$ ,

$$ab \leq \frac{a^p}{p} + \left(1 - \frac{1}{p}\right) b^{1/(1-1/p)}.$$

## Young's Integral

Let  $f(x)$  be a REAL continuous monotonic strictly increasing function on the interval  $[0, a]$  with  $f(0) = 0$  and  $b \leq f(a)$ , then

$$ab \leq \int_0^a f(x) dx + \int_0^b f^{-1}(y) dy,$$

where  $f^{-1}(y)$  is the INVERSE FUNCTION. Equality holds IFF  $b = f(a)$ .

**Young Tableau**

The YOUNG TABLEAU of a YOUNG DIAGRAM is obtained by placing the numbers  $1, \dots, n$  in the  $n$  boxes of the diagram. A “standard” Young tableau is a Young tableau in which the numbers form a non-decreasing sequence along each line and along each column. The standard Young tableaux of size three are given by  $\{\{1, 2, 3\}\}$ ,  $\{\{1, 3\}, \{2\}\}$ ,  $\{\{1, 2\}, \{3\}\}$ , and  $\{\{1\}, \{2\}, \{3\}\}$ . The number of standard Young tableaux of size  $1, 2, 3, \dots$  are  $1, 2, 4, 10, 26, 76, 232, 764, 2620, 9496, \dots$  (Sloane’s A000085). These numbers can be generated by the RECURRENCE RELATION

$$a(n) = a(n-1) + (n-1)a(n-2)$$

with  $a(1) = 1$  and  $a(2) = 2$ .

There is a correspondence between a PERMUTATION and a pair of Young tableaux, known as the SCHENSTED CORRESPONDENCE. The number of all standard Young tableaux with a given shape (corresponding to a given YOUNG DIAGRAM) is calculated with the HOOK LENGTH FORMULA. The BUMPING ALGORITHM is used to construct a standard Young tableau from a permutation of  $\{1, \dots, n\}$ .

## $z$ -Axis

The axis in 3-D CARTESIAN COORDINATES which is usually oriented vertically. CYLINDRICAL COORDINATES are defined such that the  $z$ -axis is the axis about which the azimuthal coordinate  $\theta$  is measured.

see also AXIS,  $x$ -AXIS,  $y$ -AXIS

## $z$ -Distribution

see FISHER'S  $z$ -DISTRIBUTION, STUDENT'S  $z$ -DISTRIBUTION

## $Z$ -Number

A  $Z$ -number is a REAL NUMBER  $\xi$  such that

$$0 \leq \text{frac} \left[ \left( \frac{3}{2} \right)^k \xi \right] < \frac{1}{2}$$

for all  $k = 1, 2, \dots$ , where  $\text{frac}(x)$  is the fractional part of  $x$ . Mahler (1968) showed that there is at most one  $Z$ -number in each interval  $[n, n+1)$  for integral  $n$ . Mahler (1968) therefore concluded that it is unlikely that any  $Z$ -numbers exist. The  $Z$ -numbers arise in the analysis of the COLLATZ PROBLEM.

see also COLLATZ PROBLEM

## $z$ -Score

The  $z$ -score associated with the  $i$ th observation of a random variable  $x$  is given by

$$z_i \equiv \frac{x_i - \bar{x}}{\sigma},$$

where  $\bar{x}$  is the MEAN and  $\sigma$  the STANDARD DEVIATION of all observations  $x_1, \dots, x_n$ .

## $z$ -Transform

The discrete  $z$ -transform is defined as

$$\mathcal{Z}[a] = \sum_{n=0}^{N-1} a_n z^{kn}. \quad (1)$$

The DISCRETE FOURIER TRANSFORM is a special case of the  $z$ -transform with

$$z \equiv e^{-2\pi i/N}. \quad (2)$$

A  $z$ -transform with

$$z \equiv e^{-2\pi i\alpha/N} \quad (3)$$

for  $\alpha \neq \pm 1$  is called a FRACTIONAL FOURIER TRANSFORM.

see also DISCRETE FOURIER TRANSFORM, FRACTIONAL FOURIER TRANSFORM

## References

- Arndt, J. "The  $z$ -Transform (ZT)." Ch. 3 in "Remarks on FFT Algorithms." <http://www.jjj.de/fxt/>.

## $z$ -Transform (Population)

see POPULATION COMPARISON

## $Z$ -Transform

The  $Z$ -transform of  $F(t)$  is defined by

$$\mathcal{Z}[F(t)] = \mathcal{L}[F^*(t)], \quad (1)$$

where

$$F^*(t) = F(t)\delta_T(t) = \sum_{n=0}^{\infty} F(nT)\delta(t - nT), \quad (2)$$

$\delta(t)$  is the DELTA FUNCTION,  $T$  is the sampling period, and  $\mathcal{L}$  is the LAPLACE TRANSFORM. An alternative definition is

$$Z[F(t)] = \sum_{\text{residues}} \left( \frac{1}{1 - e^{Tz} z^{-1}} \right) f(z), \quad (3)$$

where

$$f(z) = \sum_{n=0}^{\infty} F(nT) z^{-n}. \quad (4)$$

The inverse  $Z$ -transform is

$$Z^{-1}[f(z)] = F^*(t) = \frac{1}{2\pi i} \oint f(z) z^{n-1} dz. \quad (5)$$

It satisfies

$$Z[aF(t) + bG(t)] = aZ[F(t)] + bZ[G(t)] \quad (6)$$

$$Z[F(t + T)] = zZ[F(t)] - zF(0) \quad (7)$$

$$Z[F(t + 2T)] = z^2 Z[F(t)] - z^2 F(0) - zF'(0) \quad (8)$$

$$Z[F(t + mT)] = z^m Z[F(t)] - \sum_{r=0}^{m-1} z^{m-r} F(rT) \quad (9)$$

$$Z[F(t - mT)] = z^{-m} Z[F(t)] \quad (10)$$

$$Z[e^{at} F(t)] = Z[e^{-aT} z] \quad (11)$$

$$Z[e^{-at} F(t)] = Z[e^{aT} z] \quad (12)$$

$$tF(t) = -Tz \frac{d}{dz} Z[F(t)] \quad (13)$$

$$t^{-1} F(t) = -\frac{1}{T} \int_0^z \frac{f(z)}{z} dz. \quad (14)$$

Transforms of special functions (Beyer 1987, pp. 426–427) include

$$Z[\delta(t)] = 1 \quad (15)$$

$$Z[\delta(t - mT)] = z^{-m} \quad (16)$$

$$Z[H(t)] = \frac{z}{z-1} \quad (17)$$

$$Z[H(t - mT)] = \frac{z}{z^m(z-1)} \quad (18)$$

$$Z[t] = \frac{Tz}{(z-1)^2} \quad (19)$$

$$Z[t^2] = \frac{T^2 z(z+1)}{(z-1)^3} \quad (20)$$

$$Z[t^3] = \frac{T^3 z(z^2 + 4z + 1)}{(z-1)^4} \quad (21)$$

$$Z[a^{\omega t}] = \frac{z}{z - a^{\omega T}} \quad (22)$$

$$Z[\cos(\omega t)] = \frac{z \sin(\omega T)}{z^2 - 2z \cos(\omega T) + 1} \quad (23)$$

$$Z[\sin(\omega t)] = \frac{z[z - \cos(\omega T)]}{z^2 - 2z \cos(\omega T) + 1}, \quad (24)$$

where  $H(t)$  is the HEAVISIDE STEP FUNCTION. In general,

$$Z[t^n] = (-1)^n \lim_{x \rightarrow 0} \frac{\partial^n}{\partial x^n} \left( \frac{z}{z - e^{-xT}} \right) \quad (25)$$

$$= \frac{T^n z \sum_{k=1}^n \left\langle \begin{matrix} n \\ k \end{matrix} \right\rangle z^{k-1}}{(z-1)^{n+1}}, \quad (26)$$

where the  $\left\langle \begin{matrix} n \\ k \end{matrix} \right\rangle$  are EULERIAN NUMBERS. Amazingly, the  $Z$ -transforms of  $t^n$  are therefore generators for EULER'S TRIANGLE.

see also EULER'S TRIANGLE, EULERIAN NUMBER

### Zag Number

An EVEN ALTERNATING PERMUTATION number, more commonly called a TANGENT NUMBER.

see also ALTERNATING PERMUTATION, TANGENT NUMBER, ZIG NUMBER

### Zarankiewicz's Conjecture

The CROSSING NUMBER for a COMPLETE BIGRAPH is

$$\left\lfloor \frac{n}{2} \right\rfloor \left\lfloor \frac{n-1}{2} \right\rfloor \left\lfloor \frac{m}{2} \right\rfloor \left\lfloor \frac{m-1}{2} \right\rfloor,$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. This has been shown to be true for all  $m, n \leq 7$ . Zarankiewicz has shown that, in general, the FORMULA provides an upper bound to the actual number.

see also COMPLETE BIGRAPH, CROSSING NUMBER (GRAPH)

### Zariski Topology

A TOPOLOGY of an infinite set whose OPEN SETS have finite complements.

### Zaslavskii Map

The 2-D map

$$x_{n+1} = [x_n + \nu(1 + \mu y_n) + \epsilon \nu \mu \cos(2\pi x_n)] \pmod{1}$$

$$y_{n+1} = e^{-\Gamma} [y_n + \epsilon \cos(2\pi x_n)],$$

where

$$\mu = \frac{1 - e^{-\Gamma}}{\Gamma}$$

(Zaslavskii 1978). It has CORRELATION EXPONENT  $\nu \approx 1.5$  (Grassberger and Procaccia 1983) and CAPACITY DIMENSION 1.39 (Russell *et al.* 1980).

**Zeisel Number**

A number  $N = p_1 p_2 \cdots p_k$  (where the  $p_i$ s are distinct PRIMES) such that

$$p_n = Ap_{n-1} + B,$$

with  $A$  and  $B$  constants and  $p_0 \equiv 1$ . For example,  $1885 = 1 \cdot 5 \cdot 13 \cdot 29$  and  $114985 = 1 \cdot 5 \cdot 13 \cdot 29 \cdot 61$  are Zeisel numbers with  $(A, B) = (2, 3)$ .

**References**

Brown, K. S. "Zeisel Numbers." <http://www.seanet.com/~ksbrown/kmath015.htm>.

**Zeno's Paradoxes**

A set of four PARADOXES dealing with counterintuitive aspects of continuous space and time.

1. Dichotomy paradox: Before an object can travel a given distance  $d$ , it must travel a distance  $d/2$ . In order to travel  $d/2$ , it must travel  $d/4$ , etc. Since this sequence goes on forever, it therefore appears that the distance  $d$  cannot be traveled. The resolution of the paradox awaited CALCULUS and the proof that infinite GEOMETRIC SERIES such as  $\sum_{i=1}^{\infty} (1/2)^i = 1$  can converge, so that the infinite number of "half-steps" needed is balanced by the increasingly short amount of time needed to traverse the distances.
2. Achilles and the tortoise paradox: A fleet-of-foot Achilles is unable to catch a plodding tortoise which has been given a head start, since during the time it takes Achilles to catch up to a given position, the tortoise has moved forward some distance. But this is obviously fallacious since Achilles will clearly pass the tortoise! The resolution is similar to that of the dichotomy paradox.
3. Arrow paradox: An arrow in flight has an instantaneous position at a given instant of time. At that instant, however, it is indistinguishable from a motionless arrow in the same position, so how is the motion of the arrow perceived?
4. Stade paradox: A paradox arising from the assumption that space and time can be divided only by a definite amount.

**Zermelo's Axiom of Choice**

see AXIOM OF CHOICE

**Zermelo-Fraenkel Axioms**

The Zermelo-Fraenkel axioms are the basis for ZERMELO-FRAENKEL SET THEORY. In the following,  $\exists$  stands for EXISTS,  $\in$  for "is an element of,"  $\forall$  for FOR ALL,  $\Rightarrow$  for IMPLIES,  $\neg$  for NOT (NEGATION),  $\wedge$  for AND,  $\vee$  for OR,  $\Leftrightarrow$  for "is EQUIVALENT to," and  $\mathcal{S}$  denotes the union  $y$  of all the sets that are the elements of  $x$ .

1. Existence of the empty set:  $\exists x \forall u \neg (u \in x)$ .
2. Extensionality axiom:  $\forall x \forall y (\forall u (u \in x \Leftrightarrow u \in y) \rightarrow x = y)$ .
3. Unordered pair axiom:  $\forall x \forall y \exists z \forall u (u \in z \Leftrightarrow u = x \vee u = y)$ .
4. Union (or "sum-set") axiom:  $\forall x \exists y \forall u (u \in y \Leftrightarrow \exists v (v \in x \wedge u \in v))$ .
5. Subset axiom:  $\forall x \exists y \forall u (u \in y \Leftrightarrow \forall v (v \in u \rightarrow v \in x))$ .
6. Replacement axiom: For any set-theoretic formula  $A(u, v)$ ,

$$\forall u \forall v \forall w (A(u, v) \wedge A(u, w) \rightarrow v = w) \\ \rightarrow \forall x \exists y \forall v (v \in y \Leftrightarrow \exists u (u \in x \wedge A(u, v)))$$

7. Regularity axiom: For any set-theoretic formula  $A(u)$ ,  $\exists x A(x) \rightarrow \exists x (A(x) \wedge \neg \exists y (A(y) \wedge y \in x))$ .
8. AXIOM OF CHOICE:

$$\forall x [\forall u (u \in x \rightarrow \exists v (v \in u)) \\ \wedge \forall u \forall v ((u \in x \wedge v \in x \wedge \neg u = v) \\ \rightarrow \neg \exists w (w \in u \wedge w \in v)) \rightarrow \exists y \{y \subset \mathcal{S}(x) \\ \wedge \forall u (u \in x \rightarrow \exists z (z \in u \wedge z \in y) \\ \wedge \forall w (w \in u \wedge w \in y \rightarrow w = z))\}]$$

9. Infinity axiom:  $\exists x (\exists u (u \in x) \wedge \forall u (u \in x \rightarrow \exists v (v \in x \wedge u \subset v \wedge \neg v = u)))$ .

If Axiom 6 is replaced by

- 6'. Axiom of subsets: for any set-theoretic formula  $A(u)$ ,  $\forall x \exists y \forall u (u \in y \Leftrightarrow u \in x \wedge A(u))$ ,

which can be deduced from Axiom 6, then the set theory is called ZERMELO SET THEORY instead of ZERMELO-FRAENKEL SET THEORY.

Abian (1969) proved CONSISTENCY and independence of four of the Zermelo-Fraenkel axioms.

**Zernike Polynomial**

ORTHOGONAL POLYNOMIALS which arise in the expansion of a wavefront function for optical systems with circular pupils. The ODD and EVEN Zernike polynomials are given by

$$\begin{aligned} {}^oU_n^m(\rho, \phi) &= R_n^m(\rho) \frac{\sin}{\cos}(m\phi) \\ {}^eU_n^m(\rho, \phi) &= R_n^m(\rho) \frac{\sin}{\cos}(m\phi) \end{aligned} \quad (1)$$

with radial function

$$R_n^m(\rho) = \sum_{l=0}^{(n-m)/2} \frac{(-1)^l (n-l)!}{l! [\frac{1}{2}(n+m)-l]! [\frac{1}{2}(n-m)-l]!} \rho^{n-2l} \quad (2)$$

for  $n$  and  $m$  integers with  $n \geq m \geq 0$  and  $n-m$  EVEN. Otherwise,

$$R_n^m(\rho) = 0. \quad (3)$$

Here,  $\phi$  is the azimuthal angle with  $0 \leq \phi < 2\pi$  and  $\rho$  is the radial distance with  $0 \leq \rho \leq 1$  (Prata and Rusch 1989). The radial functions satisfy the orthogonality relation

$$\int_0^1 R_n^m(\rho) R_{n'}^m(\rho) \rho d\rho = \frac{1}{2(n+1)} \delta_{nn'}, \quad (4)$$

where  $\delta_{ij}$  is the KRONECKER DELTA, and are related to the BESSEL FUNCTION OF THE FIRST KIND by

$$\int_0^1 R_n^m(\rho) J_m(v\rho) \rho d\rho = (-1)^{(n-m)/2} \frac{J_{n+1}(v)}{v} \quad (5)$$

(Born and Wolf 1989, p. 466). The radial Zernike polynomials have the GENERATING FUNCTION

$$\frac{[1+z-\sqrt{1-2z(1-2\rho^2)+z^2}]^m}{(2z\rho)^m \sqrt{1-2z(1-2\rho^2)+z^2}} = \sum_{s=0}^{\infty} z^s R_{m+2s}^{\pm m}(\rho), \quad (6)$$

and are normalized so that

$$R_n^{\pm m}(1) = 1 \quad (7)$$

(Born and Wolf 1989, p. 465). The first few NONZERO radial polynomials are

$$\begin{aligned} R_0^0(\rho) &= 1 \\ R_1^1(\rho) &= \rho \\ R_2^0(\rho) &= 2\rho^2 - 1 \\ R_2^2(\rho) &= \rho^2 \\ R_3^1(\rho) &= 3\rho^3 - 2\rho \\ R_3^3(\rho) &= \rho^3 \\ R_4^0(\rho) &= 6\rho^4 - 6\rho^2 + 1 \\ R_4^2(\rho) &= 4\rho^4 - 3\rho^2 \\ R_4^4(\rho) &= \rho^4 \end{aligned}$$

(Born and Wolf 1989, p. 465).

The Zernike polynomial is a special case of the JACOBI POLYNOMIAL with

$$P_{n'}^{(\alpha, \beta)}(x) = (-1)^{n'} \frac{R_n^m(\rho)}{\rho^\alpha} \quad (8)$$

and

$$x = 1 - 2\rho^2 \quad (9)$$

$$\beta = 0 \quad (10)$$

$$\alpha = m \quad (11)$$

$$n' = \frac{1}{2}(n-m). \quad (12)$$

The Zernike polynomials also satisfy the RECURRENCE RELATIONS

$$\rho R_n^m(\rho) = \frac{1}{2(n+1)} [(n+m+2)R_{n+1}^{m+1}(\rho) + (n-m)R_{n-1}^{m+1}(\rho)] \quad (13)$$

$$R_{n+2}^m(\rho) = \frac{n+2}{(n+2)^2 - m^2} \left\{ \left[ 4(n+1)\rho^2 - \frac{(n+m)^2}{n} - \frac{(n-m+2)^2}{n+2} \right] R_n^m(\rho) - \frac{n^2 - m^2}{n} R_{n-2}^m(\rho) \right\} \quad (14)$$

$$R_n^m(\rho) + R_{n+2}^m(\rho) = \frac{1}{n+1} \frac{d[R_{n+1}^{m+1}(\rho) - R_{n-1}^{m+1}(\rho)]}{d\rho} \quad (15)$$

(Prata and Rusch 1989). The coefficients  $A_n^m$  and  $B_n^m$  in the expansion of an arbitrary radial function  $F(\rho, \phi)$  in terms of Zernike polynomials

$$F(\rho, \phi) = \sum_{m=0}^{\infty} \sum_{n=m}^{\infty} [A_n^m {}^oU_n^m(\rho, \phi) + B_n^m {}^eU_n^m(\rho, \phi)] \quad (16)$$

are given by

$$\frac{A_n^m}{B_n^m} = \frac{(n+1)}{\epsilon_{mn} 2\pi} \int_0^1 \int_0^{2\pi} F(\rho, \phi) {}^o U_n^m(\rho, \phi) {}^e U_n^m(\rho, \phi) \rho d\phi d\rho, \quad (17)$$

where

$$\epsilon_{mn} = \begin{cases} \epsilon \equiv \frac{1}{\sqrt{2}} & \text{for } m = 0, n \neq 0 \\ 1 & \text{otherwise} \end{cases} \quad (18)$$

Let a "primary" aberration be given by

$$\Phi = a'_{lmn} Y_1^{2l+m*}(\theta, \phi) \rho^n \cos^m \theta \quad (19)$$

with  $2l + m + n = 4$  and where  $Y^*$  is the COMPLEX CONJUGATE of  $Y$ , and define

$$A'_{lmn} = a'_{lmn} Y_1^{2l+m*}(\theta, \phi), \quad (20)$$

giving

$$\Phi = \frac{1}{\epsilon_{nm} 2} A_{lmn} R_n^m(\rho) \cos(m\theta). \quad (21)$$

Then the types of primary aberrations are given in the following table (Born and Wolf 1989, p. 470).

Aberration	$l$	$m$	$n$	$A$	$A'$
spherical aberration	0	4	0	$A'_{040} \rho^4$	$\epsilon A_{040} R_4^0(\rho)$
coma	0	3	1	$A'_{031} \rho^3 \cos \theta$	$A_{031} R_3^1(\rho) \cos \theta$
astigmatism	0	2	2	$A'_{022} \rho^2 \cos^2 \theta$	$A_{022} R_2^2(\rho) \cos(2\theta)$
field curvature	1	2	0	$A'_{120} \rho^2$	$\epsilon A_{120} R_2^0(\rho)$
distortion	1	1	1	$A'_{111} \rho \cos \theta$	$A_{111} R_1^1(\rho) \cos \theta$

## Zero

The INTEGER denoted 0 which, when used as a counting number, means that no objects are present. It is the only INTEGER (and, in fact, the only REAL NUMBER) which is neither NEGATIVE nor POSITIVE. A number which is not zero is said to be NONZERO.

Because the number of PERMUTATIONS of 0 elements is 1, 0! (zero FACTORIAL) is often defined as 1. This definition is useful in expressing many mathematical identities in simple form. A number *other than 0* taken to the POWER 0 is defined to be 1.  $0^0$  is undefined, but defining  $0^0 = 1$  allows concise statement of the beautiful analytical formula for the integral of the generalized SINC FUNCTION

$$\int_0^\infty \frac{\sin^a x}{x^b} dx = \frac{\pi^{1-c} (-1)^{[(a-b)/2]}}{2^{a-c} (b-1)!} \times \sum_{k=0}^{[a/2]-c} (-1)^k \binom{a}{k} (a-2k)^{b-1} [\ln(a-2k)]^c$$

given by Kogan, where  $a \geq b > c$ ,  $c \equiv a - b \pmod{2}$ , and  $[x]$  is the FLOOR FUNCTION.

The following table gives the first few numbers  $n$  such that  $n^k$  contains no zeros, for small  $k$ . The largest known  $n$  for which  $2^n$  contain no zeros is 86 (Madachy 1979), with no other  $n \leq 4.6 \times 10^7$  (M. Cook), improving the  $3.0739 \times 10^7$  limit obtained by Beeler *et al.* (1972). The values  $a(n)$  such that the positions of the right-most zero in  $2^{a(n)}$  increases are 10, 20, 30, 40, 46, 68, 93, 95, 129, 176, 229, 700, 1757, 1958, 7931, 57356, 269518, ... (Sloane's A031140). The positions in which the right-most zeros occur are 2, 5, 8, 11, 12, 13, 14, 23, 36, 38, 54, 57, 59, 93, 115, 119, 120, 121, 136, 138, 164, ... (Sloane's A031141). The right-most zero of  $2^{781,717,865}$  occurs at the 217th decimal place, the farthest over for powers up to  $2.5 \times 10^9$ .

$k$	Sloane	$n$ such that $n^k$ contains no 0s
2	007377	1, 2, 3, 4, 5, 6, 7, 8, 9, 13, 14, 15, 16, ...
3	030700	1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 12, 13, 14, ...
4	030701	1, 2, 3, 4, 7, 8, 9, 12, 14, 16, 17, 18, ...
5	008839	1, 2, 3, 4, 5, 6, 7, 9, 10, 11, 17, 18, 30, ...
6	030702	1, 2, 3, 4, 5, 6, 7, 8, 12, 17, 24, 29, 44, ...
7	030703	1, 2, 3, 6, 7, 10, 11, 19, 35, ...
8	030704	1, 2, 3, 5, 6, 8, 9, 11, 12, 13, 17, 24, 27, ...
9	030705	1, 2, 3, 4, 6, 7, 12, 13, 14, 17, 34, ...
11	030706	1, 2, 3, 4, 6, 7, 8, 9, 12, 13, 14, 15, 16, ...

While it has not been proven that the numbers listed above are the only ones without zeros for a given base, the probability that any additional ones exist is vanishingly small. Under this assumption, the sequence of largest  $n$  such that  $k^n$  contains no zeros for  $k = 2, 3, \dots$  is then given by 86, 68, 43, 58, 44, 35, 27, 34, 0, 41, ... (Sloane's A020665).

### Zero Divisor

A NONZERO element  $x$  of a RING for which  $x \cdot y = 0$ , where  $y$  is some other NONZERO element and the vector multiplication  $x \cdot y$  is assumed to be BILINEAR. A RING with no zero divisors is known as an INTEGRAL DOMAIN. Let  $A$  denote an  $\mathbb{R}$ -algebra, so that  $A$  is a VECTOR SPACE over  $\mathbb{R}$  and

$$A \times A \rightarrow A$$

$$(x, y) \mapsto x \cdot y.$$

Now define

$$Z \equiv \{x \in A : x \cdot y = 0 \text{ for some NONZERO } y \in A\},$$

where  $0 \in Z$ .  $A$  is said to be  $m$ -ASSOCIATIVE if there exists an  $m$ -dimensional SUBSPACE  $S$  of  $A$  such that  $(y \cdot x) \cdot z = y \cdot (x \cdot z)$  for all  $y, z \in A$  and  $x \in S$ .  $A$  is said to be TAME if  $Z$  is a finite union of SUBSPACES of  $A$ .

**Zillion**

A generic word for a very LARGE NUMBER. The term has no well-defined mathematical meaning. Conway and Guy (1996) define the  $n$ th zillion as  $10^{3n+3}$  in the American system (million =  $10^6$ , billion =  $10^9$ , trillion =  $10^{12}$ , ...) and  $10^{6n}$  in the British system (million =  $10^6$ , billion =  $10^{12}$ , trillion =  $10^{18}$ , ...). Conway and Guy (1996) also define the words  $n$ -PLEX and  $n$ -MINEX for  $10^n$  and  $10^{-n}$ , respectively.

see also LARGE NUMBER

**References**

Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, pp. 13–16, 1996.

**Zipf's Law**

In the English language, the probability of encountering the  $r$ th most common word is given roughly by  $P(r) = 0.1/r$  for  $r$  up to 1000 or so. The law breaks down for less frequent words, since the HARMONIC SERIES diverges. Pierce's (1980, p. 87) statement that  $\sum P(r) > 1$  for  $r = 8727$  is incorrect. Goetz states the law as follows: The frequency of a word is inversely proportional to its RANK  $r$  such that

$$P(r) \approx \frac{1}{r \ln(1.78R)},$$

where  $R$  is the number of different words.

see also HARMONIC SERIES, RANK (STATISTICS)

Goetz, P. "Phil's Good Enough Complexity Dictionary." <http://www.cs.buffalo.edu/~goetz/dict.html>.

Pierce, J. R. *Introduction to Information Theory: Symbols, Signals, and Noise*, 2nd rev. ed. New York: Dover, pp. 86–87 and 238–239, 1980.

**Zollner's Illusion**

In this ILLUSION, the VERTICAL lines in the above figure are PARALLEL, but appear to be tilted at an angle.

see also ILLUSION

**References**

Jablan, S. "Some Visual Illusions Occurring in Interrupted Systems." <http://members.tripod.com/~modularity/interr.htm>.

Pappas, T. *The Joy of Mathematics*. San Carlos, CA: Wide World Publ./Tetra, p. 172, 1989.

**Zonal Harmonic**

A SPHERICAL HARMONIC which is a product of factors linear in  $x^2$ ,  $y^2$ , and  $z^2$ , with the product multiplied by  $z$  when  $n$  is ODD.

see also TESSERAL HARMONIC

**Zone**

The SURFACE AREA of a SPHERICAL SEGMENT. Call the RADIUS of the SPHERE  $R$ , the upper and lower RADII  $b$  and  $a$ , respectively, and the height of the SPHERICAL SEGMENT  $h$ . The zone is a SURFACE OF REVOLUTION about the  $z$ -AXIS, so the SURFACE AREA is given by

$$S = 2\pi \int x \sqrt{1 + x'^2} dz. \quad (1)$$

In the  $xz$ -plane, the equation of the zone is simply that of a CIRCLE,

$$x = \sqrt{R^2 - z^2}, \quad (2)$$

so

$$x' = -z(R^2 - z^2)^{-1/2} \quad (3)$$

$$x'^2 = \frac{z^2}{R^2 - z^2}, \quad (4)$$

and

$$\begin{aligned} S &= 2\pi \int_{\sqrt{R^2 - a^2}}^{\sqrt{R^2 - b^2}} \sqrt{R^2 - z^2} \sqrt{1 + \frac{z^2}{R^2 - z^2}} dz \\ &= 2\pi R \int_{\sqrt{R^2 - a^2}}^{\sqrt{R^2 - b^2}} dz = 2\pi R(\sqrt{R^2 - b^2} - \sqrt{R^2 - a^2}) \\ &= 2\pi Rh. \end{aligned} \quad (5)$$

This result is somewhat surprising since it depends only on the height of the zone, not its vertical position with respect to the SPHERE.

**References**

Beyer, W. H. (Ed.). *CRC Standard Mathematical Tables*, 28th ed. Boca Raton, FL: CRC Press, p. 130, 1987.

**Zonohedron**

A convex POLYHEDRON whose faces are PARALLEL-sided  $2m$ -gons. There exist  $n(n-1)$  PARALLELOGRAMS in a nonsingular zonohedron, where  $n$  is the number of different directions in which EDGES occur (Ball and Coxeter

1987, pp. 141–144). Zonohedra include the CUBE, ENNEAONTAHEDRON, GREAT RHOMBIC TRIACONTAHE-  
DRON, MEDIAL RHOMBIC TRIACONTAHE-  
DRON, RHOMBIC DODECAHEDRON, RHOMBIC ICOSAHE-  
DRON, RHOMBIC TRIACONTAHE-  
DRON, RHOMBOHEDRON, and TRUN-  
CATED CUBOCTAHEDRON, as well as the entire class of  
PARALLELEPIPEDS.

Regular zonohedra have bands of PARALLELOGRAMS  
which form equators and are called “ZONES.” Ev-  
ery convex polyhedron bounded solely by PARALLELO-  
GRAMS is a zonohedron (Coxeter 1973, p. 27). Plate  
II (following p. 32 of Coxeter 1973) illustrates some  
equilateral zonohedra. Equilateral zonohedra can be  
regarded as 3-dimensional projections of  $n$ -D HYPER-  
CUBES (Ball and Coxeter 1987).

#### Zonotype

The MINKOWSKI SUM of line segments.

#### Zorn’s Lemma

If  $S$  is any nonempty PARTIALLY ORDERED SET in  
which every CHAIN has an upper bound, then  $S$  has  
a maximal element. This statement is equivalent to the  
AXIOM OF CHOICE.

see also AXIOM OF CHOICE

#### Zsigmondy Theorem

If  $1 \leq b < a$  and  $(a, b) = 1$  (i.e.,  $a$  and  $b$  are RELATIVELY  
PRIME), then  $a^n - b^n$  has a PRIMITIVE PRIME FACTOR  
with the following two possible exceptions:

1.  $2^6 - 1^6$ .
2.  $n = 2$  and  $a + b$  is a POWER of 2.

Similarly, if  $a > b \geq 1$ , then  $a^n + b^n$  has a PRIMITIVE  
PRIME FACTOR with the exception  $2^3 + 1^3 = 9$ .
